Scope and purpose

Background

The rationale behind this update on the 2016 British Society for Rheumatology (BSR) guidelines on prescribing antirheumatic drugs in pregnancy and breastfeeding [1, 2] was described in detail in the guideline scope [3]. In brief, despite the existence of additional evidence-based guidelines on prescribing/managing rheumatic disease in pregnancy [4–7] the information contained within them requires continual review to include emerging information on the safety of new and existing drugs in pregnancy.

Chronic disease adversely affects pregnancy. Data from Mothers and Babies: Reducing Risk through Audits and Confidential Enquiries across the UK (MBRRACE-UK), reports regularly from a national programme of work conducting surveillance and investigating the causes of maternal deaths, stillbirths and infant deaths [8]. Data from 2017–19 found that 8.8 women per 100 000 died during pregnancy or up to six weeks after childbirth or the end of pregnancy, and most women who died had multiple health problems or other vulnerabilities [8]. In all decisions regarding medication choices and changes, it is also important to consider the potential for deterioration in the mother's wellbeing through side effects or reduced disease control (and its adverse impact on the baby). Therefore, the exposure of the foetus to different drugs when switches are made must be balanced against possible foetal gains and understanding the potential impact of reduced control of the medical disorder on a pregnancy is vital [9].

Need for guideline

Patients with inflammatory rheumatic disease (IRD) should be counselled to achieve and then maintain remission or low disease activity before/during pregnancy to reduce the risk of adverse pregnancy outcomes [10]. This goal is primarily achieved through adjustment of therapy to ensure disease control with disease modifying anti-rheumatic drugs (DMARDs) and/or immunosuppressive drugs that are compatible with pregnancy. These medications are reviewed in the BSR guideline on prescribing drugs in pregnancy and breastfeeding: immunomodulatory anti-rheumatic drugs and corticosteroids [11]. Many patients with IRD, however, have an additional burden of pain and comorbid illness [12] that require treatment with other medications. The compatibility of various comorbidity medications relevant to rheumatic disease will be covered in this update. This updated information will provide advice for healthcare professionals and patients to ensure more confident prescribing in these scenarios and will highlight any medications that should be stopped and/or avoided in the reproductive age group unless highly effective contraception is used, in line with guidance issued by the Medicines and Healthcare Products Regulatory Agency (MHRA) and Faculty of Sexual and Reproductive Healthcare [13, 14].

Objectives of guideline

To update the previous BSR guidelines on prescribing in pregnancy in rheumatic disease for the following drug categories: pain management; NSAIDs and low-dose aspirin (LDA); anticoagulants; colchicine; dapsone; bisphosphonates; anti-hypertensives; and pulmonary vasodilators. This revised guideline was produced by consensus review of current evidence to answer specific questions in relation to each drug as follows. Should it be stopped pre-conception? Is it compatible with pregnancy? Is it compatible with breastmilk exposure? Where possible, recommendations are made regarding compatibility with paternal exposure.

Target audience

The primary audience consists of health professionals in the UK directly involved in managing patients with rheumatic disease who are (or are planning to become) pregnant and/or breastfeeding, men planning to conceive, and patients who have unintentionally conceived while taking these medications. This audience includes rheumatologists, rheumatology nurses/allied health professionals, rheumatology speciality trainees and pharmacists, as well as the patients themselves. The guideline will also be useful to obstetricians, obstetric physicians, renal physicians, dermatologists and general practitioners who may prescribe these medications to patients in pregnancy.

This guideline uses the terms 'woman', 'maternal' or 'mother' throughout. These should be taken to include people who do not identify as women but are pregnant or have given birth [15]. Where the term 'breastfeeding' is used in this guideline it also refers to infant breastmilk exposure via other methods (e.g. expressed breastmilk, administered via a bottle).

The areas the guideline does not cover

This guideline does not cover the management of infertility or acute pain relief during labour, hence morphine was excluded. Other drug categories: antimalarials; corticosteroids; disease modifying anti-rheumatic and immunosuppressive therapies; and biologic drugs are considered in another guideline [11]. All recommendations in this guideline were formulated by the working group on the basis of published evidence at the time of the systematic literature search, and do not necessarily refer to licensing information or Summary of Product Characteristics for individual medications.

Stakeholder involvement

This guideline was commissioned by the BSR Standards, Audit and Guidelines Working Group. A Guideline Working group (GWG) was created, consisting of a chair (I.G.), alongside representatives from relevant stakeholders (Table 1). In accordance with BSR policy, all members of the GWG made declarations of interest, available on the BSR website.

Involvement and affiliations of stakeholder groups involved in guideline development

The GWG consisted of rheumatologists from a range of clinical backgrounds, various allied health professionals, other specialists in women's health, lay members and representatives from the United Kingdom Tetralogy Information Service (UKTIS). All members of the working group contributed to the process for agreeing key questions, guideline content, recommendations and strength of agreement.

Rigour of development

Statement of scope of literature search and strategy employed

Most medications covered in this guideline have been comprehensively and systematically reviewed in multiple other documents, since the first BSR guideline on this topic. Therefore, a

consensus-based approach was taken to compile and assess most significant evidence published since 2013 to December 2020 through a comprehensive search of MEDLINE, PubMed and EMBASE databases with specific search terms (Supplementary Table S1, available at *Rheumatology* online). Filters were applied to capture National Institute for Health and Care Excellence (NICE) guidance, international guidelines, systematic reviews, cohort studies or case series. Information was preferentially selected from NICE guidance and/or largest/most recent systematic reviews and where lacking was extracted from largest cohort, case series or abstract. Findings were cross-referenced with the previous BSR guideline [2], as well as the Cochrane, Lactmed (a National Library of Medicine database on drugs and lactation) and UKTIS databases.

Two independent reviewers screened the title and abstract of 2997 articles, identified 130 and selected the most recent/largest systematic reviews or largest cohort study or case series as well as any NICE guidance and international guidelines. Thirty-six studies (Fig. 1) met the inclusion criteria and relevant information was extracted into data-extraction tables.

Statement of methods used to formulate the recommendations (levels of evidence)

The working group met regularly to formalise search strategy, review evidence, resolve disagreements and finally to determine recommendations. This guideline was developed in line with BSR's Guidelines Protocol using Grading of Recommendations, Assessment, Development and Evaluations (GRADE) methodology to determine quality of evidence and strength of recommendation. Accompanying each recommendation in this guideline, in brackets, is the strength of recommendation, quality of evidence and strength of agreement (SOA).

Strength of recommendation

Using GRADE, recommendations were categorized as either strong (denoted by 1) or weak (denoted by 2), according to the balance between benefits and risks. A strong recommendation was made when the benefits clearly outweigh the risks (or vice versa). A weak recommendation denotes that the benefits are more closely balanced with the risk, or more uncertain.

Quality of evidence

Using the GRADE approach, the quality of evidence was determined as either high (A), moderate (B) or low/very low (C) reflecting the confidence in the estimates of benefits or harm.

Strength of agreement

The wording of each recommendation was discussed until all members were satisfied they would score at least 80 on a scale of 1 (no agreement) to 100 (complete agreement) and then 20/23 members with full voting rights scored each recommendation on the same scale and the average was calculated to generate a strength of agreement (SOA) score. Two patient representatives and a data-analyst expressed concern that they did not have sufficient medical knowledge of all drugs reviewed to score all recommendations, so while they fully agreed with each, they did not wish to score each one and did not contribute to the final SOA score.

Statement of any limits of search and when guideline will be updated

The search was conducted in December 2020. Limits were placed for English language and filters as described above. The guideline will be updated in five years.

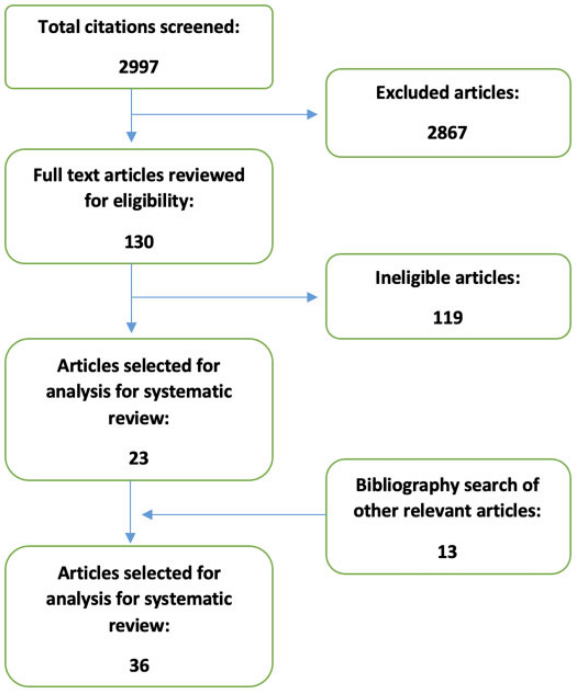

Figure 1. Flow diagram of study selection

The guideline

Drugs are considered in the following categories: pain management; NSAIDs and LDA in the management of multisystem rheumatic disease; anticoagulants; bisphosphonates; antihypertensive medication in the management of multisystem rheumatic disease; and pulmonary vasodilators. The overall findings for maternal and foetal breastmilk exposures to each drug, including information and key references from the previous BSR guideline [2] are summarised and recommendations updated accordingly. Paternal exposures and recommendations are described separately after maternal data. An overall summary of compatibility of each drug pre-conception, during pregnancy, breastmilk exposure and paternal exposure is shown in Table 2. Generic recommendations were developed based on evidence as shown in Supplementary Table S2, available at *Rheumatology* online.

Generic recommendations on prescribing in rheumatic disease in pregnancy

i) Pre-conception counselling should be addressed by all healthcare professionals, with referral to professionals with relevant experience as appropriate to optimize all therapy, including non-pharmacological options for chronic pain management during pregnancy (GRADE 1A, SOA 99.5).
ii) The risks and benefits of drug treatment to mother and foetus should be discussed and clearly documented by all healthcare professionals involved in the patient's care (GRADE 1A, SOA 99).
iii) The cause of pain and other symptoms should be assessed and managed appropriately (GRADE 1B, SOA 98.5).
iv) The requirement for analgesia should be assessed and minimum effective dose should be prescribed and titrated according to response (GRADE 1B, SOA 100).
v) Tricyclic antidepressants are preferred over other anti-depressant medications to manage chronic pain (GRADE 1B, SOA 98.1).
vi) Cessation of anti-depressant therapy that is being used as chronic pain medication in the post-natal period is not recommended, due to the risk of adverse impact on mood (GRADE 1C, SOA 96).
vii) LDA (≤150 mg/day) is recommended in all patients at high risk for pre-eclampsia (GRADE 1A, SOA 99.5).
viii) Low molecular weight heparin (LMWH) is the preferred anticoagulant (GRADE 1A, SOA 100).
ix) Nifedipine is the preferred vasodilator (GRADE 1B, SOA 98.5).
x) Paternal drug exposure may reduce male fertility but has not been associated with adverse foetal development or pregnancy outcome. Although evidence is weak, we recommend that men are reassured about the safety of fathering a pregnancy while taking medicines to manage comorbidities as described in this guideline (GRADE 1C, SOA 98).

Pain management: conventional analgesics

Paracetamol

Two systematic reviews [16, 17] were selected. Overall, paracetamol was considered to have a favourable safety profile in pregnancy. Potential links between paracetamol use in pregnancy and pre-term birth and adverse neurodevelopmental outcomes (principally autism and attention deficit hyperactivity disorder) were confounded by maternal disease and selection bias [16]. UKTIS states that 'In most studies, risk of abnormal neurodevelopment correlated with duration of paracetamol exposure. However, significant methodological limitations of these studies limit the conclusions that can be drawn, and a causal association remains unproven' [18].

There were no convincing associations with congenital malformations. UKTIS notes that findings of a possible increased risk of cryptorchidism in male offspring following paracetamol use during pregnancy are conflicting [18]. Current Royal College of Obstetricians (RCOG) guidance is that paracetamol remains safe for use during pregnancy and breastfeeding, and its use in any trimester does not appear to increase the risk of major birth defects [19].

There were conflicting results on the risk of developing wheeze in infants exposed to paracetamol during pregnancy. A recent meta-analysis of 13 articles and 1 043 109 individuals identified a statistically significant association between prenatal paracetamol exposure and increased risk of child asthma [odds ratio (OR) 1.19; 95% CI, 1.12, 1.27; $P < 0.00001$] in a random-effect model [17]. This significant association was observed for first trimester as well as second and third trimester exposure.

There were no studies identified which specifically examined neonatal outcomes after drug exposure in breastmilk. LactMed [20] reports low amounts of this drug in breastmilk at levels much less than doses usually given to infants with few reports of adverse events. The following recommendations for paracetamol were developed based on evidence as shown in Supplementary Table S3, available at *Rheumatology* online.

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

Table 2. Summary of drug compatibility in pregnancy and breastfeeding

	Compatible peri-conception	Compatible with 1st trimester	Compatible with 2nd/3rd trimester	Compatible with breastfeeding	Compatible with paternal exposure
Conventional painkillers					
Paracetamol	Yes	Yes[a]	Yes[a]	Yes	Yes[b]
Codeine	Yes	Yes	Yes	Yes[a]	Yes[b]

Bisphosphonates					
Bisphosphonates	Stop 3 months in advance	No	No	No data	Yes[b]
Antihypertensives					
ACEi/ARBs	Stop when pregnancy confirmed		Exceptional circumstances only	Yes (enalapril)[c]	Yes[b]
Nifedipine	Yes	Yes <90 mg/day	Yes <90 mg/day	Yes	Yes[b]
Amlodipine	Yes[c]	Yes[c]	Yes[c]	Yes[c]	Yes[b]
Labetalol*	Yes	Yes	Yes	Yes	Yes[b]
Methyldopa*	Yes	Yes	Yes	Yes	Yes[b]
Pulmonary vasodilators					
Sildenafil		Multi-disciplinary team assessment		No data	Yes[b]
Bosentan		Multi-disciplinary team assessment		No data	Yes[b]
Prostacyclines		Multi-disciplinary team assessment		No data	Yes[b]

For further information and caveats, see relevant recommendations and main text in Executive Summary and full Guideline.
[a] Intermittent use advised – see main text for details.
[b] Based on limited data and no association with adverse foetal development or pregnancy outcome; therefore, unlikely to be harmful.
[c] Limited evidence, but unlikely to be harmful.
[d] Limited evidence regarding use for treatment of chronic pain in pregnancy. High-dose folic acid (5 mg/day) recommended.
[e] Cessation of anti-depressant therapy in post-natal period is not recommended.
[f] Possible association with miscarriage and malformation.
* Drugs not included in original search, but added due to relevance.

Recommendations for paracetamol in pregnancy and breastfeeding

i) Paracetamol is the analgesic of choice and compatible peri-conception and throughout pregnancy (GRADE 1B, SOA 99).
ii) LactMed describes paracetamol as a good choice for analgesia and fever reduction in breastfeeding mothers (GRADE 2C, SOA 99.5).

Codeine

One systematic review [16] considered outcomes from opioid-exposed pregnancies, including three studies of congenital malformation in >20 000 codeine-exposed pregnancies with conflicting results. Of these three studies, a large Norwegian population-based cohort study [21] found no statistically significant associations between neonatal codeine exposure and congenital malformations. In contrast, a large case-control study found that first trimester exposure to opioids (codeine and hydrocodone in 69% of cases) was significantly associated with congenital heart defects, spina bifida and gastroschisis [22], although there was a high risk for recall bias in this study. A case-control study found a significant association between spina bifida in infants and first trimester maternal opioid use, although it was not with codeine use

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

specifically and potential confounders such as illicit drug use/dependence and sociodemographic data exist in this study [23]. UKTIS notes that the methodological limitations of studies make it difficult to draw any firm conclusions and more robust research is needed before firm conclusions regarding the risk of congenital anomalies with codeine use can be provided [18].

No convincing associations between first trimester opioid use and miscarriage have been found. A large population study found increased rates of premature delivery, reduced birthweight and pre-eclampsia in codeine-exposed patients compared with controls that was considered to be due to confounding factors such as maternal disease and lack of adjustment for gestational age [21]. This study also found a significant increase in post-partum haemorrhage (18.3% *vs* 14.5%; OR 1.3; 95% CI 1.1, 1.5) in 2666 mothers exposed to codeine [21] and hypothesized it was due to an opioid effect weakening myometrial contraction, but the precise mechanism is unknown.

UKTIS describes theoretical concerns that maternal use of codeine near term may be associated with respiratory depression in the neonate and notes that the only study that has investigated the risk of neonatal respiratory depression found no increased risk [18]. The potential risk of neonatal abstinence syndrome (NAS) is lower with short courses of short-acting opioids and must be weighed against the benefits for treating acute pain that often outweigh risks. Prolonged opioid use, however, should be avoided and if used in the last trimester, neonatologists should be advised due to the risks of NAS [16].

Controversy remains over whether codeine is safe in breastfeeding. Central nervous system (CNS) depression was reported by mothers in 16.7% (35/210) babies exposed to codeine, compared with 0.5% exposed to paracetamol [24]. In the same study there was one neonatal death and high morphine levels were found at post-mortem. The mother had received high doses of codeine (>2 mg/kg/day) and was subsequently found to be an ultra-rapid CYP2D6 metaboliser. Another study demonstrated dose-dependent CNS depression in 24% (17/72) of infants exposed to codeine through breastmilk [25]. A large study of 7804 infants reported conflicting results, but specifically, there was no difference in poor Apgar scores, postnatal complications, admission to special care baby units, readmission to hospital, resuscitation or death in infants exposed and not exposed to codeine [26].

LactMed notes that numerous professional organizations and regulatory agencies recommend that other agents are preferred over codeine during breastfeeding but that other opioid alternatives have been less studied and may not be safer [20]. It is acknowledged that due to its unpredictable metabolism, administration of codeine results in delivery of an unknown quantity of morphine. Therefore, despite its widespread use and probable safety in most cases, we would advise caution with prolonged use of codeine in breastfeeding and appropriate advice to the mother to seek medical attention if she has any concerns regarding lethargy or drowsiness in her child. The following recommendations for codeine were based on evidence as shown in Supplementary Table S3, available at *Rheumatology* online.

Recommendations for codeine in pregnancy and breastfeeding

i) Codeine is compatible peri-conception and throughout pregnancy, although long-term use should be avoided. There is no consistent evidence to recommend a dose reduction pre-delivery but neonatologists should be aware of maternal use (GRADE 1B, SOA 97.8).
ii) Caution is advised with use of codeine in breastfeeding, due to the risk of CNS depression resulting from unpredictable metabolism of codeine to morphine (GRADE 1C, SOA 98).

Tramadol

A systematic review [16] considered outcomes from tramadol-exposed pregnancies. It included a large prospective cohort study of over 1.6 million women [27] that reported a statistically significant association between tramadol use in pregnancy and major congenital malformations (OR 1.33; 95% CI 1.05, 1.70) and cardiovascular defects (OR 1.56; 95% CI 1.04, 2.29), although it did not adjust for indication, duration or dose of medication.

UKTIS notes that a single study identified an increased risk of miscarriage among women who used tramadol in early pregnancy and recommended further studies considering the impact of confounding factors to clarify this finding. A single cohort study found no increased risk of preterm delivery within 146 pregnancies exposed to tramadol in at least the first trimester [18]. A small number of case reports have reported NAS with long-term intrauterine exposure to tramadol [28], although none have compared the relative rate of NAS with tramadol compared with other opioid analgesics.

LactMed states that the excretion of tramadol into milk is low and even lower amounts of the active metabolite, O-desmethyltramadol, are excreted and a study of breastfeeding in newborn infants found no adverse effects attributable to tramadol compared with controls [20]. There has been one death, however, in the 8-month-old breastfed infant of a woman addicted to tramadol, although the death was not definitely attributable to tramadol exposure in breastmilk [29]. Current RCOG advice states that tramadol can continue to be used (with caution) during breastfeeding and the lowest effective dose should be used for the shortest time possible [19]. The following recommendations for tramadol were based on evidence as shown in Supplementary Table S3, available at *Rheumatology* online.

Recommendations for tramadol in pregnancy and breastfeeding

i) Avoid tramadol peri-conception and in first trimester and only consider in second/third trimester if no alternative analgesia (GRADE 2B, SOA 97.8).
ii) Based on limited data, tramadol may be compatible with short-term use in breastfeeding (GRADE 2C, SOA 94.8).

Other treatments for chronic pain

Amitriptyline

NICE guidance [30] and a systematic review [16] described amitriptyline use in pregnancy. Notably, the evidence base underlying amitriptyline use in pregnancy comes from its use as a tricyclic antidepressant (TCA) to treat depression at doses of 150–300 mg and evidence of its use in pregnancy to treat chronic widespread pain at 75 mg per day or less is lacking. In addition, most studies report on TCAs as a drug class and although they include (some) women exposed to amitriptyline, they lack a separate assessment of their pregnancy outcomes so do not provide information about specific amitriptyline exposure [18].

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

Overall, no increased risk of congenital malformations has been found for TCAs [16]. UKTIS reports conflicting findings, with possible associations with spontaneous abortion, preterm delivery, and autism spectrum disorder identified in some (but not all) studies [18]. There is an association between discontinuation of antidepressants and a high risk for relapse of mood disorders that can adversely impact on pregnancy. It is unknown, however, whether a similar phenomenon of rebound pain exists when antidepressants used for analgesia are discontinued in pregnancy, particularly for amitriptyline that is used at 2–4-fold higher doses to treat depression compared with chronic pain. If a decision is made to stop amitriptyline in pregnancy, the dose should be tapered gradually where possible [16, 30].

Low levels of amitriptyline and its metabolites are reported in breastmilk with no adverse effects described with limited follow-up, summarised in LactMed [20]. The following recommendations were based on evidence as shown in Supplementary Table S4, available at *Rheumatology* online.

Recommendations for amitriptyline in pregnancy and breastfeeding

i) Amitriptyline is compatible with pregnancy. There is no evidence of adverse effect on IQ or developmental outcomes (GRADE 1C, SOA 100).
ii) Because very little amitriptyline is found in breastmilk with antidepressant doses and it is used at lower doses for chronic pain, it is unlikely to cause adverse effects in breastfed infants (GRADE 1C, SOA 100).

Gabapentin and pregabalin

Data on gabapentin use in pregnancy comes mostly from studies of the treatment of maternal epilepsy at doses generally higher that those used to treat chronic pain, while information on pregabalin use in pregnancy comes from studies of its use to treat neuropathic pain [18]. A systematic review [16] of gabapentin use in pregnancy to treat epilepsy did not find any evidence of an increased rate of major malformations or other adverse outcomes attributable to gabapentin exposure. No long-term outcomes were reported. Furthermore, a systematic review and meta-analysis published in abstract form only [31], of eight cohort studies (four prospective and four retrospective), reporting 5 072 286 unexposed and 949 exposed pregnancies found that first trimester exposure to gabapentin was not statistically significantly associated with major congenital malformations (OR 0.83; 95% CI 0.45, 1.53).

A prospective cohort study using Teratology Information Services data from seven European countries [32] found that first trimester use of pregabalin was associated with significantly higher rates of major congenital malformations when compared with unexposed pregnancies (OR 3.0; 95% CI 1.2, 7.9). This study, however, was limited by a small sample size (164 exposed pregnancies) and lack of adjustment for potential confounding by use of concomitant medications [16]. A systematic review of pregabalin use, mostly to treat neuropathic pain in pregnancy, including data from this study and two others identified 651 pregnancy exposures and concluded that pregabalin exposure during pregnancy is not devoid of structural teratogenicity potential [33]. UKTIS reviewed data from six controlled studies, with outcomes of >3000 exposed pregnancies of patients with chronic pain or other non-epilepsy indications. They conclude that this data does not indicate that maternal pregabalin use in pregnancy is associated with increased risks of malformation, miscarriage or adversely affects foetal growth [18]. Interestingly, a systematic review and meta-analysis published in abstract form only [34], of six studies reporting 2319 exposed pregnancies and 4 982 778 unexposed pregnancies found that first trimester exposure to pregabalin was not significantly associated with an increased risk of major congenital malformations (OR 1.20; 95% CI 0.92, 1.57).

Following completion of our guidelines, the MHRA issued a safety warning on the use of pregabalin in pregnancy based on new data available online [35]. This new data has been considered in the latest UKTIS update in April 2022 that states that the available data do not provide conclusive evidence that maternal pregabalin use in the first trimester, or at any stage of pregnancy, is associated with increased risks of either overall malformation or any specific malformations. Therefore, our recommendations have not changed.

UKTIS found no controlled studies of the risk of neonatal complication following prenatal gabapentin or pregabalin exposure, although one study has described a small number of affected infants, including one case of neonatal withdrawal following *in-utero* pregabalin exposure [18]. Use of any centrally acting drug throughout pregnancy or near delivery may be associated with withdrawal symptoms in the neonate and/or NAS.

Although evidence is lacking and it is uncertain if pregabalin or gabapentin impact upon maternal folate status, UK guidelines state that women who take any anti-epileptic medication should be prescribed high-dose folic acid (5 mg/day) preconceptually and in the first trimester [19].

There remains limited data on use of these drugs in breastfeeding. According to LactMed, low levels of gabapentin and pregabalin have been found in breastmilk with no adverse effects on infants reported in limited case reports/series ($n < 10$) for gabapentin. Therefore, both drugs may be considered if required by the breastfeeding mother [20]. The following recommendations were based on evidence as shown in Supplementary Table S4, available at *Rheumatology* online.

Recommendations for gabapentin and pregabalin in pregnancy and breastfeeding

i) Gabapentin at lowest effective dose may be considered in pregnancy with folic acid supplementation if no alternative analgesic is suitable (GRADE 1B, SOA 95).
ii) Gabapentin may be considered in breastfeeding if no alternative analgesic is suitable (GRADE 2C, SOA 96).
iii) Pregabalin may be considered in pregnancy (with folic acid supplementation) and during breastfeeding (GRADE 2C, SOA 95.3).

Serotonin–norepinephrine reuptake inhibitors (SNRIs)

NICE guidance [30] and two systematic reviews [16, 33] described SNRI use in pregnancy. There was no association between first trimester exposure to venlafaxine and an increased risk for major congenital malformations [16]. UKTIS notes that although there are some reports of an increased risk of miscarriage following gestational exposure to venlafaxine, the data are inconsistent and likely confounded by indication and other factors [18]. Some studies have found a possible association with an increased risk for some perinatal complications, including a withdrawal syndrome with venlafaxine use in the

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

third trimester [16]. A more limited data set for duloxetine does not suggest a clinically important increased risk for major malformations but has identified prenatal antidepressant exposure syndrome in two of five case reports and conflicting reports of increased rates of gestational hypertension and spontaneous abortion [33].

LactMed reports that infants receive venlafaxine and its active metabolite in breastmilk, and the metabolite of the drug can be found in the plasma of most breastfed infants, but no proven drug-related side effects have been reported in small case series. Little published information is available on the use of duloxetine during breastfeeding; however, the dose in milk is low and serum levels were low in two breastfed infants [20]. The following recommendations were based on evidence as shown in Supplementary Table S4, available at *Rheumatology* online.

Recommendations for SNRIs in pregnancy and breastfeeding

i) Venlafaxine is compatible at conception and throughout pregnancy. There may be an increased risk of neonatal abstinence syndrome/short-term behavioural effects, but larger studies are needed to evaluate this finding (GRADE 2C, SOA 95.8).
ii) Duloxetine may be considered in pregnancy and breastfeeding but there are fewer data than for venlafaxine (GRADE 2C, SOA 95.3).
iii) Venlafaxine and duloxetine may be considered in breastfeeding if there is no alternative chronic pain medication (GRADE 2C, SOA 95.8).

Selective serotonin reuptake inhibitors (SSRIs)

NICE guidance [30] and a systematic review [16] described SSRI use to treat depression in pregnancy. The SSRIs are used to treat chronic pain at similar doses used to treat depression. A systematic review considered data from >50 000 infants exposed to SSRIs *in utero*, which did not show an overall increased risk for congenital malformations [16]. It describes ongoing debate about the risk for cardiovascular malformations with first-trimester use of SSRIs with risk found from some [36, 37] but not all studies [38, 39]. Overall, any increase in absolute risk was thought unlikely to be clinically significant and may be associated with particular SSRIs, principally fluoxetine and paroxetine [36, 37].

The UKTIS summary of findings to date from studies on SSRIs states that a causal association between use of SSRIs in pregnancy and any type of congenital malformation has not been confirmed. It also describes conflicting results from other outcomes and concludes that available data do not suggest that SSRI use in pregnancy increases the risk of stillbirth and that possible associations with neurodevelopmental impairment in infants requires further study. An increased risk, however, of persistent pulmonary hypertension (PPHN) of the newborn has also been reported following exposure to SSRIs as a class beyond 20 weeks of gestation and, although it remains an uncommon event (0.2–1.2% *vs* 0.1–0.2% in the background population), it represents a potentially serious neonatal complication [18]. Because there is no robust evidence of a superior safety profile for any one drug, switching between drugs is not recommended if depression is stable on treatment.

NICE recommendations on use of TCAs, SSRIs or SNRIs include consideration of: the uncertainty about whether any increased risk to the foetus and other problems for the woman or baby can be attributed directly to these drugs or may be caused by other factors; and the risk of discontinuation symptoms in the woman and neonatal adaptation syndrome in the baby with most TCAs, SSRIs and (S)NRIs, in particular paroxetine and venlafaxine [30].

There is limited information on the use of these drugs in breastfeeding. One small study showed temporarily reduced growth during exposure to fluoxetine in breastmilk. There have been no studies specifically investigating compatibility of paroxetine and sertraline with breastfeeding, but sertraline is reported as having one of the lowest rates of transmission to breastmilk [20]. The following recommendations were based on evidence as shown in Supplementary Table S4, available at *Rheumatology* online.

Recommendations for SSRIs in pregnancy and breastfeeding

i) Fluoxetine, paroxetine and sertraline are compatible with pregnancy (GRADE 1B, SOA 98.8).
ii) Based on limited evidence, SSRIs are compatible with breastfeeding (GRADE 2C, SOA 98.3).

NSAIDs and anti-platelet drugs

Non-selective cyclooxygenase (COX) inhibitors have different indications in pregnancy. NSAIDs have analgesic and anti-inflammatory actions mediated through peripheral inhibition and differential selectivity of COX enzymes. In contrast, LDA at doses ≤150 mg/day is used to prevent thrombosis and pre-eclampsia in high-risk groups throughout pregnancy in patients with rheumatic diseases. Clopidogrel is an anti-platelet agent that may sometimes be used with or instead of LDA to reduce cardiovascular risk. NICE guidance [40], four systematic reviews [16, 41–43] and a case report/review [44] evaluated LDA, NSAID and clopidogrel use in pregnancy.

NSAIDs and COX-2 inhibitors

Overall, there is no consistent evidence for an increased risk of teratogenic effects with NSAID use in pregnancy. There are mixed findings regarding a potential increased risk for miscarriage, with findings limited by methodology and larger associations reported for indomethacin and diclofenac use in the periconceptional period [16]. There was no information on safety of COX2 inhibitors in pregnancy. NSAIDs are reported to increase the incidence of luteinized unruptured follicle (LUF) syndrome, whereby an anovulatory cycle results due to failure of normal follicular wall rupture despite normal ovarian follicular development and elevation of serum progesterone. COX-2 is active in the ovaries during follicular development; thus, inhibition via COX-2 inhibitors is thought to result in LUF. Although similar findings have been reported for both COX-1 and COX-2 NSAIDs, the risks have been found to be greater in patients with inactive disease and in those taking a COX-2 inhibitor (etoricoxib) rather than non-selective NSAIDs and it is reversible, following drug withdrawal [16].

A systematic review of the effects of various drugs on foetal cardiac function evaluated by ultrasound found that all NSAIDs (including COX2 inhibitors) increased constriction in the ductus arteriosus, within 4–30 h of exposure and resolved by 72 h of discontinuation [43]. In this study the critical gestational age (measured for indomethacin)

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

increased from 5–10% of foetuses at weeks 26–27 to 50% at week 32.

In 2020 the United States Food and Drug Administration (FDA) recommended that all NSAIDs be avoided from gestational week 20 rather than the previously advised 30 weeks. This advice was based on their updated review of published data to 2016 and 35 cases reported to FDA identifying an increased risk of oligohydramnios and renal impairment that began at 20 weeks of gestation and were mostly reversible on stopping NSAID. They clarify their advice for healthcare professionals, stating that the use of NSAIDs between 20 and 30 weeks of pregnancy should be limited to the lowest effective dose for the shortest duration [45].

Low-dose aspirin

LDA has been extensively studied and shown to improve outcomes in high-risk pregnancies. A Cochrane review of 77 trials, involving 40 249 women and their babies, found high quality evidence that antiplatelet agents (mostly LDA up to 150 mg/day) reduced pre-eclampsia and its complications [42]. A systematic review of 22 RCTS of LDA plus heparin compared with other treatments in patients with APS, including 1515 treatment and 1531 control subjects, found that adverse pregnancy outcomes were significantly improved with LDA and heparin [41]. The use of LDA in the third trimester of pregnancy is not associated with premature closure of ductus arteriosus and NICE guidelines for management of hypertension in pregnancy advises treatment with LDA until delivery [40].

Clopidogrel

There was no demonstrable maternofoetal toxicity in 13 (mostly second and third trimester only) pregnancy exposures to clopidogrel [44]. UKTIS does not report on clopidogrel.

LactMed considers various non-selective NSAIDs to be acceptable during breastfeeding and prefers ibuprofen because of its extremely low levels in breastmilk, short half-life and safe use in infants in doses much higher than those excreted in breastmilk, as an analgesic or anti-inflammatory agent in breastfeeding mothers. There was no information on COX2 inhibitors. Aspirin doses up to 325 mg daily are not excreted into breastmilk so LDA may be considered as an antiplatelet drug for use in breastfeeding women and is preferred to clopidogrel as no information is available on this drug [20]. Recommendations for these drugs were based on evidence as shown in Supplementary Tables S5 and S6, available at *Rheumatology* online.

Recommendations for NSAIDs and COX-2 inhibitors in pregnancy and breastfeeding

i) Discordant findings from retrospective, large studies with population controls on the use of non-selective NSAIDs in the first trimester of pregnancy raise the possibility of a low risk of miscarriage and malformation. Therefore, these drugs should only be used intermittently in the first trimester of pregnancy (GRADE 1B, SOA 97.3).

ii) Intermittent rather than regular use of all non-selective NSAIDs except LDA is recommended throughout pregnancy and weaned from end of second trimester (26 weeks) to stop by gestational week 30 to avoid premature closure of the ductus arteriosus (GRADE 1B, SOA 98).

iii) At present there are limited data on selective cyclooxygenase-2 inhibitors; they should therefore be avoided during pregnancy (GRADE 2C, SOA 98.5).

iv) Non-selective NSAIDs (especially ibuprofen) are compatible with breastfeeding (GRADE 1C, SOA 98.8).

Recommendations for LDA and clopidogrel in pregnancy and breastfeeding

i) LDA may be continued throughout pregnancy and NICE guidelines (2019) for hypertension in pregnancy advise treatment with LDA (for prophylaxis of pre-eclampsia) until delivery (GRADE 1B, SOA 99.0).

ii) LDA is compatible with breastfeeding (GRADE 2C, SOA 99.8).

iii) There are limited data on clopidogrel but it may be considered where alternative drugs are not suitable in pregnancy and breastfeeding (GRADE 2C, SOA 96.3).

Colchicine and dapsone

These drugs were not considered in the previous BSR guideline and are now included because they may be used to treat certain inflammatory rheumatic diseases. UKTIS does not report on colchicine or dapsone. A systematic review and meta-analysis of colchicine use in 550 pregnancies of women with mostly familial Mediterranean fever (FMF) at doses of 1–2 mg per day, compared with 1263 non-exposed pregnancies found this drug did not significantly increase the incidence of foetal malformations or miscarriage when taken during pregnancy [46]. However, the National Amyloidosis Centre recommends to continue the prescribed dose as there are no established safety concerns at colchicine doses >2 mg daily during pregnancy [47].

No systematic review data was identified for dapsone. A review of 924 pregnancies exposed to dapsone to treat malaria was precluded from meaningful risk-benefit analysis due to limited reporting of outcomes [48]. They concluded that the use of dapsone may be considered when no suitable alternative is available and the threat of malaria is the greater risk. It is a safe option in pregnant patients without glucose-6-phosphate dehydrogenase (G6PDH) deficiency and can be used during lactation while monitoring the baby for haemolysis and G6PDH deficiency [49]. A review of the treatment of rheumatic and autoimmune skin disease in women during pregnancy concluded that dapsone may be safely and cautiously used during pregnancy [50].

LactMed reports that long-term prophylactic maternal doses of colchicine up to 1.5 mg daily produce levels in milk that result in the infant receiving <10% of the maternal weight-adjusted dosage and no adverse effects have been reported from limited studies. It also states that the highest milk levels occur 2–4 h after a dose, so avoiding breastfeeding during this time can minimize the infant dose, or simply taking the drug after nursing. LactMed also states that dapsone can be used during breastfeeding; however, haemolytic anaemia might occur, especially in newborn infants and in those with G6PDH deficiency [20]. Recommendations for these drugs were based on evidence as shown in Supplementary Table S5, available at *Rheumatology* online.

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

Recommendations for colchicine and dapsone in pregnancy and breastfeeding

i) Colchicine therapy may be considered during pregnancy (GRADE 1B, SOA 99.5).
ii) Dapsone may be used in pregnancy (GRADE 2C, SOA 95.0).
iii) Colchicine may be used in breastfeeding (GRADE 2C, SOA 98.3).
iv) Dapsone may be used in breastfeeding and due to the risk of haemolytic anaemia it is advised to monitor the infant for signs of haemolysis, especially in newborn or premature breastfed infants (GRADE 2C, SOA 90.7).

Anticoagulants in rheumatic disease

The deleterious effects of warfarin and compatibility of heparin in pregnancy are well described and evidence-based guidelines for the management of venous thromboembolism (VTE) and thrombophilia in pregnancy exist [51].

Heparin

A systematic review [41] and systematically produced guidelines [52] describe the utility of heparin in the management of VTE and pregnancy morbidity in pregnant patients with antiphospholipid syndrome (APS). Heparin/LMWH does not cross the placenta [1, 2].

Heparins are compatible with breastfeeding. There were no additional studies identified, but LactMed states that no particular caution is required as the molecular weight of heparin is such that it is unlikely to be appreciably excreted into breastmilk.

Warfarin

Warfarin has the ability to cross the placenta and is associated with an increased risk of congenital abnormalities including a characteristic warfarin embryopathy (hypoplasia of the nasal bridge, congenital heart defects, ventriculomegaly, agenesis of the corpus callosum, stippled epiphyses) in ~5% of foetuses exposed between 6 and 12 weeks of gestation. Warfarin should therefore be avoided between 6 and 12 weeks [51]. While heparin/LMWH remains the anticoagulant of choice in pregnancy for the majority of patients considered to be at increased thrombotic risk in pregnancy, warfarin may be considered in pregnancy for women with mechanical heart valves (MHVs). The LMWH regimen could be used for those who refuse warfarin and other vitamin K antagonists (VKAs) [53]. In management of atrial fibrillation, VKAs may be used after the first trimester [54].

LactMed is reassuring both with regard to low drug levels in breastmilk and infant serum, and no reported adverse effects.

New anticoagulants

A systematic review [55] identified 236 cases of direct oral anticoagulants (DOAC) use in pregnancy of rivaroxaban ($n = 178$), dabigatran ($n = 27$), apixaban ($n = 21$) and edoxaban ($n = 10$). DOACs were mostly used for prophylaxis or treatment of venous thromboembolism ($n = 91$). DOACs were discontinued within the first 2 months of pregnancy in 84%, and the maximum reported duration of use was 26 weeks. Pregnancy outcome data were available for 140 pregnancies. Thirty-nine pregnancies were electively terminated. In the remaining 101 pregnancies, total miscarriage rate was 31% ($n = 31$) and live birth rate was 68% ($n = 69$, one missing). Foetal and neonatal abnormalities were reported in eight pregnancies, of which at least half were suspected to be related to rivaroxaban use during the first trimester of pregnancy. In only 18% of cases ($n = 42$), the presence or absence of thrombotic and bleeding complications was reported. This limited evidence raises concern regarding embryo-foetal safety, with a high incidence of miscarriages and a 4% rate of congenital anomalies with the use of rivaroxaban. Overall, not enough data are available to judge safety and efficacy of the use of DOACs during pregnancy and rivaroxaban and dabigatran have both been shown to cause adverse obstetric outcomes in animal studies, described in summary of product characteristics [56, 57]. UKTIS does not report on DOACs.

LactMed describes several case reports that consistently indicate that maternal doses of rivaroxaban of 15–30 mg daily produce low levels in milk that are considerably below doses required for anticoagulation in infants [20]. Therefore, breastfeeding is not contraindicated if rivaroxaban is required by the mother. There are no data on the excretion of dabigatran into human milk.

Fondaparinux

Fondaparinux may be considered if there is an allergy or adverse response to LMWH, although solid data are lacking and minor transplacental passage has been demonstrated, without any adverse materno-foetal effects in five pregnancies [58]. LactMed considers use of fondaparinux to be acceptable during breastfeeding [20]. Recommendations on all anticoagulants were based on evidence as shown in Supplementary Table S6, available at *Rheumatology* online.

Recommendations for anticoagulants in pregnancy and breastfeeding

i) LMWH heparin is compatible throughout pregnancy (GRADE 1A, SOA 100).
ii) LMWH is compatible with breastfeeding (GRADE 1C, SOA 100).
iii) The use of warfarin in pregnancy is associated with increased foetal risk throughout pregnancy and has limited indications, therefore should only be considered in exceptional circumstances (GRADE 1B, SOA 98.8).
iv) Warfarin is compatible with breastfeeding (GRADE 1A, SOA 100).
v) Direct oral anticoagulants (DOACs) cannot be recommended in pregnancy (GRADE 1C, SOA 97.9).
vi) Rivaroxaban may be considered in breastfeeding (GRADE 2C, SOA 95.3).
vii) Other DOACs are not recommended in breastfeeding due to lack of human data and concerns from animal studies (GRADE 1C, SOA 97.4).
viii) Fondaparinux may be considered in pregnancy and breastfeeding if there is an allergy or adverse response to LMWH (GRADE 2C, SOA 95.5).

Bisphosphonates

Bisphosphonates are not ideal in women planning pregnancy because the absolute risk of fracture is small in this age group and the skeletal half-life of these drugs is very long. The number of human pregnancy exposures remains limited and a detailed literature review identified 40 pregnancies [59], while a systematic review published in abstract form described

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

outcomes from 120 bisphosphonate-exposed pregnancies [60]. Overall, rates of congenital malformation and miscarriages were comparable in bisphosphonate and controls, although limiting factors included: few comparator groups; heterogeneous maternal disease; concomitant medication; and small sample size. Controlled studies have demonstrated possible associations between preconceptual/gestational bisphosphonate exposure and increased risk of spontaneous abortion, decreased infant birth weight, and lower gestational age at delivery. These findings, however, may reflect data limitations and/or uncontrolled confounding (UKTIS). Therefore, further controlled studies are required to fully establish the safety of bisphosphonates in pregnancy and they are not drugs of choice in women planning pregnancy.

LactMed states that limited evidence indicates that breastfeeding after cessation of long-term bisphosphonate treatment appears to have no adverse effects on the infant. There is no information on the use of alendronate or risedronate during breastfeeding. Limited information indicates that maternal doses of pamidronate of 30 mg intravenously produce very low levels in milk and because pamidronate has a serum half-life of ~3 h, is highly bound to calcium and poorly absorbed orally, absorption of pamidronate by a breastfed infant is unlikely. Therefore, withholding breastfeeding for 12–24 h after a dose should ensure that the breastfed infant is exposed to little or no pamidronate. If the mother receives a bisphosphonate during pregnancy or nursing, some experts recommend monitoring the infant's serum calcium during the first 2 months postpartum [20]. These recommendations were based on evidence as shown in Supplementary Table S7, available at *Rheumatology* online.

Recommendations for bisphosphonates in pregnancy and breastfeeding

i) There is insufficient data upon which to recommend bisphosphonates in pregnancy or to advise a specific time for them to be stopped pre-conception. Given their biological half-life in bone of up to 10 years and no evidence of harm from limited reports of their use in pregnancy, a pragmatic recommendation is that they should be stopped 3 months in advance of pregnancy (GRADE 2C, SOA 96.8).
ii) There are no data on which to base a recommendation for the use of bisphosphonates during breastfeeding (GRADE 2C, SOA 98.5).

Antihypertensive medication in rheumatic disease

Patients with ARD, particularly renal SLE and systemic sclerosis (SSc) frequently require anti-hypertensive treatment for sometimes life-threatening disease, such as scleroderma renal crisis, that may require specialist use of certain antihypertensive drugs. The introduction of ACEis for the treatment of SSc renal crisis has significantly reduced mortality rates of up to 50% in the 1970s to a mortality of up to 20% at 6 months after introducing ACEis. The use of ACEis may therefore be indicated (also in pregnancy) in exceptional circumstances [7].

The management of pre-existing and new onset hypertension in pregnancy has been comprehensively reviewed and updated in the 2019 NICE guideline, Hypertension in Pregnancy: Diagnosis and Management [40].

Angiotensin blockade

Disruption of the renin-angiotensin system (RAS) in pregnancy by maternal treatment with ACEis or angiotensin receptor blockers (ARBs) in the second/third trimester leads to abnormal foetal renal development, known as foetal RAS blockade syndrome [61]. There are conflicting results, however, on the risk of this fetopathy occurring after first trimester exposure. A systematic review and meta-analysis [62] of 19 articles involving 4 163 753 pregnant women found a significant association between overall congenital malformations and first trimester-only exposure to ACEis/ARBs (odds ratio 1.94; 95% CI 1.71, 2.21; $P < 0.0001$). This review also found a significant association between cardiovascular malformations, miscarriage and stillbirth and ACEi/ARB exposure. A similar risk was observed in a cohort of 1 333 624 pregnancies [63], including 4107 (0.31%) following first trimester ACEi exposure that found an increased risk of overall malformations in the ACEi-exposed pregnancies [unadjusted relative risk (RR), 1.82; 95% CI 1.61, 2.06] and of cardiac malformations (RR 2.95; 95% CI 2.50, 3.47). On further analysis, however, restricting the cohort to pregnancies complicated by chronic hypertension (both exposed and unexposed) and accounting for other confounding factors, there was no significant increase in the risk of any of the outcomes assessed.

NICE guidelines state that women taking ACEis/ARBs should be advised of the increased risk of congenital anomalies if these drugs are taken during pregnancy and to discuss alternative antihypertensive drugs with their clinician responsible for managing their condition [40]. If they become pregnant on ACEis/ARBs they should be stopped (preferably within 2 working days of notification) and other antihypertensive treatments offered. UKTIS recommends that where prolonged first trimester exposure has occurred, a 20-week anomaly scan should focus on cardiovascular, renal and neurological development, in addition to the routine anatomical checks. UKTIS states that ACEi fetopathy following exposure to ACEis in the second and third trimesters of pregnancy is well-described and may include oligohydramnios, renal tubular dysgenesis, neonatal anuria, hypocalvaria, pulmonary hypoplasia, persistent patent ductus arteriosus, mild-to-severe intrauterine growth restriction, and foetal or neonatal death. It is proposed that these effects occur as a result of a direct effect on the foetal RAS which begins to function from ~26 weeks gestation. A small prospective case series has suggested that the risk period for ACEi fetopathy is with exposure beyond 20 weeks gestation. Due to data limitations, the absolute risk of ACEi fetopathy is unclear. Due to the risk of ACEi fetopathy, use of ACEis in the second and third trimesters is generally contraindicated and should only be reserved for cases of severe maternal illness that cannot be managed using alternative drugs [18].

Negligible amounts of enalapril and captopril are transferred into breastmilk with no adverse effects reported on the breastfed infants of mothers treated with short-acting ACEis [64]. NICE states that enalapril may be offered to treat hypertension in breastfeeding mothers with appropriate monitoring of maternal renal function and serum potassium [40]. The following recommendations were based on evidence as shown in Supplementary Table S8, available at *Rheumatology* online.

Recommendations for ACEis/ARBs in pregnancy and breastfeeding

i) ACEis and ARBs should be stopped as soon as possible when pregnancy is confirmed in the first trimester and if

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

necessary an alternative antihypertensive compatible with pregnancy given (GRADE 1A, SOA 100).
ii) ACEis/ARBs should be avoided in the second and third trimester but may be considered under specialist advice in certain circumstances (GRADE 1C, SOA 98.5).
iii) Based on limited evidence, enalapril is compatible with breastfeeding (GRADE 2C, SOA 98.5).

Calcium channel blockers

Calcium channel blockers (CCBs) including amlodipine, diltiazem, felodipine, lacidipine, lercanidipine, nicardipine, nifedipine, nimodipine and verapamil are mainly used for the treatment and prophylaxis of angina, and the treatment of hypertension where an ACEi/ARB is unsuitable. In patients with rheumatic disease, nifedipine or amlodipine are also used to treat Raynaud's phenomenon.

UKTIS has not identified an increased risk of congenital malformations or other adverse pregnancy outcomes with CCBs, although data remains too limited to draw firm conclusions on many outcomes. Data on rates of preterm delivery, foetal growth and neurodevelopmental outcomes are too limited and/or confounded to permit an accurate risk assessment, but where a CCB is required to treat maternal hypertension or as a tocolytic, foetal benefits of use are likely to outweigh any unspecified risk and treatment should not be withheld on this basis [18]. Data is more limited for amlodipine so it is not included in alternatives to treat hypertension in pregnancy that include labetalol, nifedipine or methyldopa in order of preference [40].

LactMed describes low levels of nifedipine and amlodipine in breastmilk, without any adverse effects being reported among exposed infants [20]. NICE guidance of other antihypertensive drugs that may be offered in breastfeeding mothers include nifedipine, amlodipine, atenolol or labetolol [40]. Recommendations were based on evidence as shown in Supplementary Table S8, available at *Rheumatology* online.

Recommendations for CCBs in pregnancy and breastfeeding

i) Nifedipine is compatible with pregnancy with no direct evidence of harm at doses up to 90 mg/day (GRADE 1A, SOA 99.0).
ii) Nifedipine is compatible with breastfeeding (GRADE 1B, SOA 100).
iii) Amlodipine can be considered in pregnancy and breastfeeding as there is no evidence of harm (GRADE 1C, SOA 97.9).

Pulmonary vasodilators

Moderate-to-severe pulmonary hypertension (PHT) is a rare complication of certain ARDs and remains a contraindication to planned pregnancy with high mortality. Unintentional pregnancy and/or patient choice, however, means that treatment of this condition with specific pulmonary vasodilators may be required in pregnancy. Limited information on use of these drugs in human pregnancy was identified in the previous BSR guideline [2]. No studies were identified examining pregnancy outcomes after paternal exposure to any of these pulmonary vasodilators.

Sildenafil

Sildenafil has been studied in the context of trying to improve utero-placental circulation in pregnancies affected by severe foetal growth restriction. A systematic review and meta-analysis were identified, examining the utility of sildenafil being used for treatment or prevention of obstetric diseases compared with placebo. They analysed 598 pregnant women from seven clinical trials with pre-eclampsia ($n = 139$), intrauterine growth restriction ($n = 275$) and oligohydramnios ($n = 184$) and found a significant improvement in birthweight following sildenafil treatment during pregnancy, with no difference in other outcomes [65].

However, in 2018 a randomised controlled study looking at using sildenafil to treat pregnant women in whom there was significant foetal growth restriction was halted early due to a number of neonates having persistent pulmonary hypertension of the newborn (PPHN). This multi-centered study enrolled women with a singleton pregnancy between 18 and 30 weeks with severe foetal growth restriction of likely placental origin, where the likelihood of perinatal death/severe morbidity was estimated to be significant. Participants were randomised into sildenafil or placebo arms. One of three study sites reported that PPHN appeared to be more prevalent in infants exposed *in utero* to sildenafil compared with placebo-exposed infants ($n = 17/93$ *vs* $n = 3/90$), that death among infants with PPHN was more common following sildenafil exposure ($n = 11/17$ *vs* $n = 0/3$), and that when the overall neonatal death rate was considered, there was a non-statistically significant trend towards an increased risk following sildenafil exposure ($n = 19/93$ *vs* $n = 9/90$). As a result, the trial was halted early and sildenafil is no longer recommended to improve placental function in severely growth-restricted babies [66, 67].

However, it should be noted that two further study sites for this trial did not detect an increased risk of PPHN and overall, this trial has not identified a clear beneficial effect of sildenafil on foetal outcome. PPHN is more prevalent in premature and growth-restricted foetuses and is a relatively rare complication in healthy babies delivered at term.

UKTIS recommends that general use of sildenafil in pregnancy should be avoided where possible [18]. However, in the context of maternal pulmonary hypertension there is clear benefit in the use of sildenafil to reduce the effects of pulmonary hypertension, which often gets worse during pregnancy. Case studies/case series data suggest that sildenafil exposure was not associated with miscarriage or congenital anomaly; however, the data is extremely limited (around 18 reported pregnancies). The risks and benefits of continuing sildenafil should be discussed with the patients, but most will likely require ongoing treatment.

LactMed describes limited data showing that sildenafil and its active metabolite are poorly excreted into breastmilk and amounts ingested by the infant are small and would not be expected to cause any adverse effects in breastfed infants [20].

Bosentan

Animal data have revealed teratogenicity due to bosentan, including malformations of the head, mouth, face and large blood vessels in addition to an increased number of stillbirths and increased mortality [68]. Previously, we identified data from 12 pregnancies of women with PHT treated with bosentan in pregnancy plus multiple other medications, including sildenafil and iloprost, with reduced pregnancy duration of 37 weeks in one and reduced birth weight in two cases but no other maternal complications or foetal loss [2]. We identified one further case report of a patient with Eisenmenger

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

syndrome exposed to long-term bosentan before and during pregnancy that was delivered by caesarean section at 27 weeks due to severe maternal PHT without any evidence of teratogenic effects of bosentan [69]. UKTIS does not report on bosentan.

LactMed states there is little published experience with bosentan during breastfeeding and an alternate drug may be preferred, especially while nursing a newborn or preterm infant [20].

Prostacyclines

Previously we identified data on 23 pregnancies of patients with PHT (three with SLE) treated with iloprost ($n = 5$ pregnancies) or epoprostenol ($n = 15$ pregnancies) and three other prostacyclines (unspecified type) in patients who were taking multiple other medications, including immunosuppressants, sildenafil and bosentan [2]. Findings of premature deliveries and reduced birthweight were confounded by maternal disease. Furthermore, maternal complications were attributable to PHT. We did not identify any new evidence and UKTIS and LactMed do not report on iloprost or epoprostenol. The recommendations were based on evidence as shown in Supplementary Table S7, available at *Rheumatology* online.

Recommendations for pulmonary vasodilators in pregnancy and breastfeeding

i) Established moderate to severe PHT remains a contraindication to pregnancy. If pregnancy occurs, the use of these pulmonary vasodilator drugs in pregnancy should be considered only as part of a multidisciplinary team assessment (GRADE 1C, SOA 99.5).
ii) Limited evidence supports the use of prostacyclines to treat PHT during pregnancy (GRADE 2C, SOA 98.0).
iii) Limited evidence supports the use of sildenafil to treat PHT during pregnancy (GRADE 2C, SOA 98.0).
iv) Bosentan is teratogenic in animals and although there is no evidence of harm from human pregnancy, the evidence is insufficient to recommend in pregnancy (GRADE 1C, SOA 98.8).
v) There are no data relating to breastfeeding exposure to pulmonary vasodilators on which to base a recommendation (GRADE 2C, SOA 98.8).

Paternal exposures

There remains limited data on paternal exposure to drugs used to treat rheumatic disease and reports of teratogenic effects linked with paternal exposure are lacking for all drugs considered in this guideline. Our updated search revealed the following additional information.

Links with adverse neurodevelopmental outcomes [70] but not asthma [71] have been reported following paternal exposure to paracetamol from the largest cohort study of paracetamol in pregnancy. A direct causal effect, however, remains unproven.

An observational prospective cohort study from Sweden [72] of 3983 children born to fathers receiving antidepressant treatment around conception, included fathers treated with: SSRIs, $n = 2865$; SNRIs, $n = 470$; and TCAs, $n = 240$. This study found paternal intake of all antidepressants studied to be safe with respect to the risk of preterm birth, malformation, autism or intellectual disability.

A systematic review of the effect of paternal exposure to immunosuppressive drugs on sexual function, reproductive hormones, fertility, pregnancy and offspring outcomes [73] found very weak evidence of reduced sperm parameters with codeine, tramadol and CCBs but not NSAIDs, LDA or ACEi and no abnormalities in offspring were reported for any drug. Interestingly, low-dose lisinopril (2.5 mg/day) has been shown to increase total sperm count and motility in a randomised, controlled, crossover pilot of study of normotensive men with idiopathic oligospermia leading to an unassisted pregnancy rate of 48.5% [74]. Small studies of chronic use of NSAIDs in men with rheumatic disease have not indicated any impairment of spermatogenesis and no evidence for harmful effects of NSAIDs on offspring [75].

A systematic review [76] of eight studies including 166 cases of paternal exposure found inconsistent reports of adverse effects of colchicine on sperm quality and only one study ($n = 53$) of paternal exposure did not find an adverse effect on offspring [77].

The following recommendations were based on evidence as shown in Supplementary Table S9, available at *Rheumatology* online.

Recommendations for paternal exposure

i) Paracetamol is compatible with paternal exposure (GRADE 1B, SOA 98.5).
ii) Amitriptyline, SNRIs and SSRIs are compatible with paternal exposure (GRADE 1B, SOA 98.5).
iii) Non-selective NSAIDs are compatible with paternal exposure (GRADE 1C, SOA 98.4).
iv) Based on limited or no data and no association with adverse foetal development or pregnancy outcome, paternal exposure to all other drugs described in this guideline are unlikely to be harmful (GRADE 2C, SOA 97.3).

Applicability and utility

Implementation

Awareness of these guidelines will aid clinical practitioners and patients in decision making and will be raised through presentation at local, regional and national meetings. No barriers to implementation of these guidelines are anticipated.

Key standards of care

Patients with rheumatic disease should receive tailored pre-pregnancy counselling and then be reviewed during pregnancy and the four month post-partum period by clinical practitioners with expertise in the management of rheumatic disease in pregnancy, in addition to their routine obstetric care. They should have access to written information on relevant medications in pregnancy and breastfeeding that is accurate and allows them to make informed decisions regarding compatibility of certain drugs in pregnancy.

Future research agenda

The limitation of current evidence highlights the need for a national pregnancy registry for patients with rheumatic disease, as currently exists for women with epilepsy. All women with rheumatic disease who become pregnant would be eligible to register, whether or not they are on anti-rheumatic treatment. The prospective pregnancy outcome data would then be published to display information on outcomes such as miscarriage and congenital anomalies in patients treated with

Downloaded from https://academic.oup.com/rheumatology/advance-article/doi/10.1093/rheumatology/keac552/6783013 by guest on 03 February 2023

anti-rheumatic and other drug therapy. These data would also be used to answer specific questions where data is currently lacking. Data relating to the impact of paternal exposure to these drugs (both fertility and male-mediated teratogenicity), as well as breastfeeding exposure is particularly limited, and further research in these areas is urgently required.

Mechanism for audit of the guideline

An audit pro forma to assess compliance with these guidelines is shown in Supplementary Data S1, available at *Rheumatology* online.

Supplementary data

Supplementary data are available at *Rheumatology* online.

Data availability statement

All relevant data produced during the guideline development process are presented in the guideline or in the accompanying supplementary material.

Funding

No specific funding was received from any bodies in the public, commercial or not-for-profit sectors to carry out the work described in this manuscript.

Disclosure statement: All authors have made declarations of interest in line with BSR policy (see Supplementary Material, available at *Rheumatology* online). L.M. has received honoraria from UCB and educational funding support from Abbvie and Pfizer. C.G. has received honoraria from Abbvie, Alumis, Amgen, Astra-Zeneca, MGP, Sanofi and UCB. C-S.Y. has received honoraria from Amgen. K.S. has received educational support from UCB and honoraria from UCB and Thermo-Fisherworks and Novo Nordic Foundation research grant. L.W. has received honorarium from Novartis. M.D.R. has received educational funding support from Lilly, Pfizer, Janssen and UCB and honoraria from Lilly, Menarini and Biogen. S.T. has received honoraria from UCB. I.G. has received honoraria and unrestricted research grants from UCB. K.H. has received honoraria and educational support from UCB. M.G. has received honoraria from UCB, Lily and Abbvie. M.K. is an employee of GSK and gave independent expert advice to the working group. The remaining authors have declared no conflicts of interest.

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the clinician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes, but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision, as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The American College of Rheumatology is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To develop an evidence-based guideline on contraception, assisted reproductive technologies (ART), fertility preservation with gonadotoxic therapy, use of menopausal hormone replacement therapy (HRT), pregnancy assessment and management, and medication use in patients with rheumatic and musculoskeletal disease (RMD).

Methods. We conducted a systematic review of evidence relating to contraception, ART, fertility preservation, HRT, pregnancy and lactation, and medication use in RMD populations, using Grading of Recommendations Assessment, Development and Evaluation methodology to rate the quality of evidence and a group consensus process to determine final recommendations and grade their strength (conditional or strong). Good practice statements were agreed upon when indirect evidence was sufficiently compelling that a formal vote was unnecessary.

Results. This American College of Rheumatology guideline provides 12 ungraded good practice statements and 131 graded recommendations for reproductive health care in RMD patients. These recommendations are intended to guide care for all patients with RMD, except where indicated as being specific for patients with systemic lupus erythematosus, those positive for antiphospholipid antibody, and/or those positive for anti-Ro/SSA and/or anti-La/SSB antibodies. Recommendations and good practice statements support several guiding principles: use of safe and effective contraception to prevent unplanned pregnancy, pre-pregnancy counseling to encourage conception during periods of disease quiescence and while receiving pregnancy-compatible medications, and ongoing physician-patient discussion with obstetrics/gynecology collaboration for all reproductive health issues, given the overall low level of available evidence that relates specifically to RMD.

Conclusion. This guideline provides evidence-based recommendations developed and reviewed by panels of experts and RMD patients. Many recommendations are conditional, reflecting a lack of data or low-level data. We intend that this guideline be used to inform a shared decision-making process between patients and their physicians on issues related to reproductive health that incorporates patients' values, preferences, and comorbidities.

INTRODUCTION

The management of reproductive health issues in patients with rheumatic and musculoskeletal diseases (RMD) differs from that in healthy persons. As a result, rheumatologists and other clinicians caring for these patients must often discuss with and counsel their patients about contraception, pregnancy and lactation (including medications), assisted reproductive technology (ART), fertility preservation, and hormone replacement therapy (HRT), and they must collaborate with specialists in the fields of obstetrics-gynecology, maternal-fetal medicine, and reproductive endocrinology and infertility.

Pregnancy in women with RMD may lead to serious maternal or fetal adverse outcomes; accordingly, contraception, tailored to the individual patient with emphasis on safety and efficacy, should be discussed and encouraged. Because risk for pregnancy complications depends on diagnosis, disease activity and damage, medications, and the presence of anti-Ro/SSA, anti-La/SSB, and antiphospholipid (aPL) antibodies, pre-pregnancy assessment is critical to informing pregnancy management, therapy, and outcomes. The ability to become pregnant may itself be an independent concern for some patients, so minimizing risk of gonadal insufficiency is important. RMD patients with subfertility value advice from their rheumatologists about oocyte preservation and in vitro fertilization (IVF).

It is difficult to avoid use of medication during pregnancy in patients with RMD. Not all medications are safe for preconception use by men and women or during pregnancy and lactation, but uncontrolled systemic inflammatory disease is itself associated with poor pregnancy outcomes (1–6). In addition, patients are vulnerable to disease flare postpartum (7,8), but the American Academy of Pediatrics recommends that infants be exclusively breastfed for 6 months (9). In many cases medication safety is uncertain because most data are derived from case reports, small series, and observational studies; direct data from randomized controlled trials are scarce. As a result, identifying the appropriate screening and management (including medication use) for RMD patients is challenging for clinicians.

Given the primary goal of providing recommendations for care of all adult RMD patients throughout the reproductive lifespan, the scope of this guideline is broad. There has been little attention to aspects of reproductive health care other than pregnancy in patients with RMD, and the American College of Rheumatology (ACR) recognizes the imperative for guidance in reproductive health issues for these patients.

Submitted for publication July 3, 2019; accepted in revised form December 10, 2019.

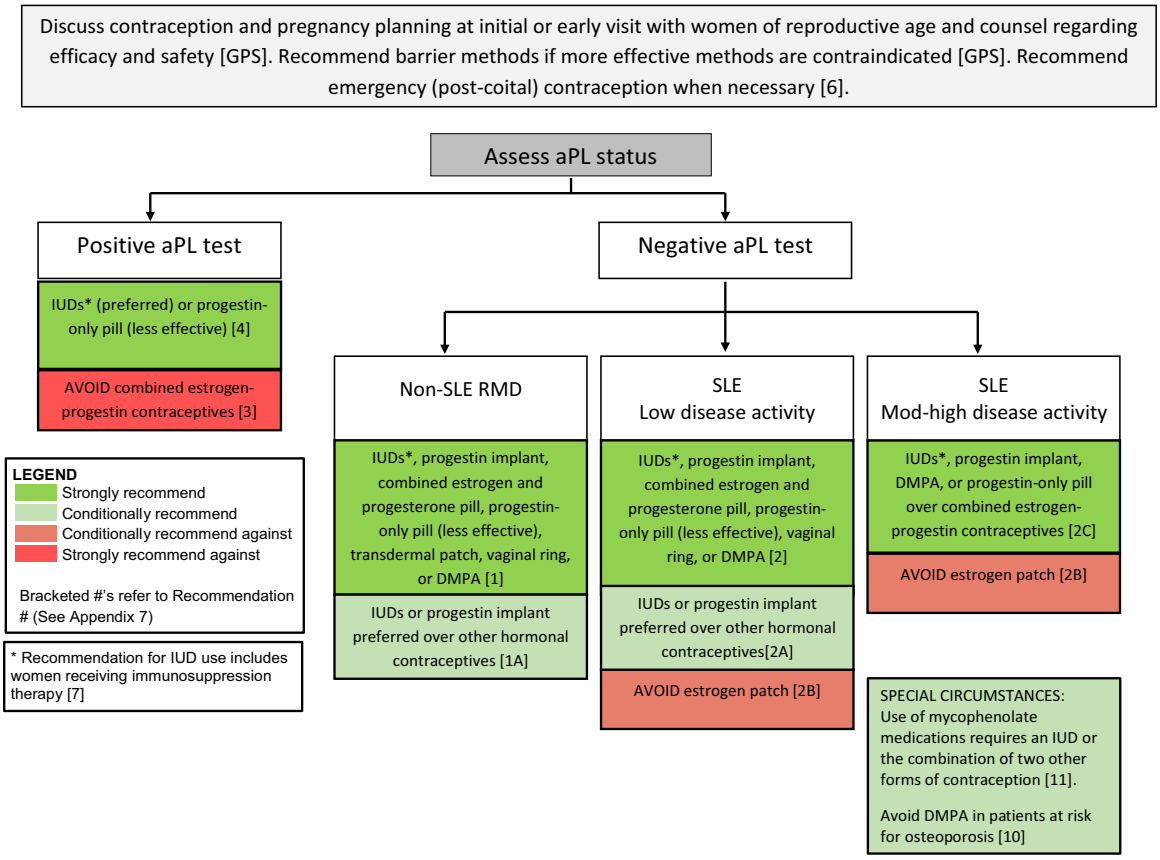
METHODS

These recommendations follow the ACR guideline development process, using a systematic literature review and Grading of Recommendations Assessment, Development and Evaluation methodology (for details, see Supplementary Appendices 1, 2, and 3, available on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). When no direct data on RMD patients were available from the systematic literature review, discussion and voting were supplemented with indirect data collected in additional, less formal literature reviews (Supplementary Appendix 4, http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) performed by Core Team members (Supplementary Appendix 5, http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract); these data were not part of the systematic literature review and are listed as "not graded" in evidence tables. Results of the systematic literature review were compiled in an Evidence Report (Supplementary Appendix 6, http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract).

A *strong recommendation* suggests that most informed patients would choose the recommended management. While usually reflecting a higher level of evidence, it may also reflect the severity of a potential negative outcome. A *conditional recommendation* suggests that choice will vary with individual values and preferences. Conditional recommendations generally reflect a lack of data, limited data, or conflicting data that lead to uncertainty. Finally, *good practice statements* are those for which indirect evidence is sufficiently compelling that a formal vote is unnecessary. They are presented as "suggestions" rather than formal recommendations. Recommendation numbers are denoted in Supplementary Appendix 7 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) as numbers in parentheses, allowing for cross-referencing of recommendations with tables/appendices, and referencing the order in the original list (i.e., may not be consecutive in the supplementary appendix.)

RESULTS/RECOMMENDATIONS

The detailed tables of recommendations appear in Supplementary Appendix 7 (available on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Concise recommendations within this appendix and throughout the article are grouped into categories of contraception,



Discuss contraception and pregnancy planning at initial or early visit with women of reproductive age and counsel regarding efficacy and safety [GPS]. Recommend barrier methods if more effective methods are contraindicated [GPS]. Recommend emergency (post-coital) contraception when necessary [6].
Assess aPL status
Positive aPL test
Negative aPL test
IUDs* (preferred) or progestin-only pill (less effective) [4]
AVOID combined estrogen-progestin contraceptives [3]
Non-SLE RMD
SLE
Low disease activity
SLE
Mod-high disease activity
IUDs*, progestin implant, combined estrogen and progesterone pill, progestin-only pill (less effective), transdermal patch, vaginal ring, or DMPA [1]
IUDs or progestin implant preferred over other hormonal contraceptives [1A]
IUDs*, progestin implant, combined estrogen and progesterone pill, progestin-only pill (less effective), vaginal ring, or DMPA [2]
IUDs or progestin implant preferred over other hormonal contraceptives[2A]
AVOID estrogen patch [2B]
IUDs*, progestin implant, DMPA, or progestin-only pill over combined estrogen-progestin contraceptives [2C]
AVOID estrogen patch [2B]

* Recommendation for IUD use includes women receiving immunosuppression therapy [7]
SPECIAL CIRCUMSTANCES:
Use of mycophenolate medications requires an IUD or the combination of two other forms of contraception [11].
Avoid DMPA in patients at risk for osteoporosis [10]

Figure 1. Recommendations and good practice statements (GPS) for use of contraception in women with rheumatic and musculoskeletal disease (RMD). aPL = antiphospholipid antibody (persistent moderate [Mod]–to-high–titer anticardiolipin or anti–β_2-glycoprotein I antibody or persistent positive lupus anticoagulant); IUDs = intrauterine devices (copper or progestin); SLE = systemic lupus erythematosus; DMPA = depot medroxyprogesterone acetate.

ART, fertility preservation with gonadotoxic therapy, use of menopausal HRT, pregnancy assessment and management, and medication use (compatibilities for paternal, maternal, and breastfeeding use are reported).

Most recommendations are general; when relevant, RMDs are specifically identified, most often for systemic lupus erythematosus (SLE) or according to presence of specific autoantibodies (aPL and anti-Ro/SSA and anti-La/SSB antibodies). In general, testing for aPL should be performed in patients with SLE or SLE-like disease and in patients with suggestive histories or physical findings; whether to check these antibodies in other RMD patients with a lower likelihood of positive results should be decided by physician-patient discussion. The presence of aPL modifies the recommendations in many circumstances, and therefore is considered separately. "Positive aPL" throughout this guideline refers to laboratory criteria only (10): persistent (2 positive test results at least 12 weeks apart) moderate-high–titer anticardiolipin antibody (aCL) (≥40 units or ≥99th percentile), moderate-high–titer anti–β_2-glycoprotein I (anti-β_2GPI) (≥40 units or ≥99th percentile), or positive lupus anticoagulant (LAC).

Detailed definitions of aPL and antiphospholipid syndrome (APS) are presented in Supplementary Appendix 8 (available on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Briefly, included within the positive aPL group are patients with asymptomatic aPL who have no history of thrombosis or pregnancy morbidity (i.e., meet laboratory but not clinical APS criteria), patients with obstetric APS (OB APS), and patients with thrombotic APS. OB APS refers to patients who meet laboratory criteria for APS and have experienced prior pregnancy complications consistent with APS (with other causes ruled out). These include 3 consecutive losses prior to 10 weeks' gestation, a fetal loss at or after 10 weeks' gestation, or delivery at <34 weeks due to preeclampsia, intrauterine growth restriction, or fetal distress. Thrombotic APS refers to patients who meet laboratory criteria for APS and have experienced a prior thrombotic event (arterial or venous), regardless of whether they have had obstetric complications. The aPL definitions in the guideline include both patients with and patients without other underlying autoimmune disease, unless specifically stated.

Patients with lower-titer aCL and/or anti-β_2GPI (or non-criteria aPL) who do not meet laboratory classification criteria may still have some degree of risk that is difficult to quantify. Recommendations for these patients are not offered in this guideline; decisions regarding therapy rest on discussion between the patient and the physician, taking into account additional relevant risk factors.

Contraception

Supplementary Appendix 7, Table A (on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal recommendations regarding contraception; strength of evidence and justifications for strong and conditional recommendations are shown in Supplementary Appendix 9 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Figure 1 details the contraception decision-making

Table 1. Safety and efficacy of various contraceptive methods in women with RMD*

Method	Safety in women with RMD	1-year failure rate, %†
Highly effective (LARC)		
Copper IUD	Safe in all women with RMD; may increase menstrual bleeding	<1
Progestin IUD	Safe in all women with RMD; may decrease menstrual bleeding	<1
Progestin implant	Limited data, but likely safe in all women with RMD	<1
Effective		
Progestin-only pill (daily)	Safe in all women with RMD; higher rate of breakthrough bleeding than with combined contraceptives; must take same time every day for efficacy	5–8
DMPA (IM injection every 12 weeks)	Safe in most women with RMD; exceptions: positive aPL, at high risk for OP	3
Combined estrogen and progesterone pill (daily)	Safe in most women with RMD; exceptions: positive aPL, very active SLE	5–8
Transdermal patch (weekly)	Safe in most women with RMD; exceptions: positive aPL, SLE; serum estrogen levels higher than with pill or vaginal ring	5–8
Vaginal ring (monthly)	Safe in most women with RMD; exceptions: positive aPL, very active SLE	5–8
Less effective		
Diaphragm	Safe in all women with RMD	12
Condom	Safe in all women with RMD; only form to prevent STD	18
Fertility awareness–based methods‡	Safe in all women with RMD; limited efficacy, especially if menses are irregular	24
Spermicide	Safe in all women with RMD; use with condoms or diaphragm to improve efficacy	28

* RMD = rheumatic and musculoskeletal disease; LARC = long-acting reversible contraception; IUD = intrauterine device; DMPA = depot medroxyprogesterone acetate; IM = intramuscular; aPL = antiphospholipid antibody; OP = osteoporosis; SLE = systemic lupus erythematosus; STD = sexually transmitted disease.
† Percent of women who will become pregnant within the first year of typical use.
‡ Methods based on the timing of the menstrual cycle.

process, and Table 1 provides efficacy data and comments on available contraceptives.

RMD patients typically underutilize effective contraception (11–13). The most important reason for effective contraception in women with RMD is to avoid risks of unplanned pregnancy, which include worsening disease activity that may threaten maternal organ function or life, adverse pregnancy outcomes (pregnancy loss, severe prematurity, and growth restriction), and teratogenesis. Members of a 1-day patient focus group, convened as part of the guideline process, emphasized their desire that clinicians caring for patients with RMD routinely discuss family planning, as they view their rheumatologists as "the doctors who know them and their medications best." We suggest that rheumatologists treating reproductive-age women with RMD discuss contraception and pregnancy plans at an initial or early visit and periodically thereafter, and always when initiating treatment with potentially teratogenic medications. One Key Question (www.powertodecide.org) has been suggested in the literature as a simple way of addressing the issue of family planning with patients: "Would you like to become pregnant in the next year?" (14). In whatever way one chooses to discuss this topic, counseling regarding contraception should include issues of efficacy and safety, with consideration of individual values and preferences.

Effectiveness of reversible forms of contraception varies. For long-acting reversible contraceptives (copper or progestin intrauterine devices [IUDs]) and subdermal progestin implants), ideal use and "real-world" use effectiveness are similar, with pregnancy rates of <1% per year ("highly effective"). Combined estrogen-progestin methods, depot medroxyprogesterone acetate (DMPA) injections, and progestin-only pills yield pregnancy rates of 3–8% per year ("effective") (15,16). Condoms, fertility-based methods (e.g., "rhythm"), and spermicide are less effective and yield pregnancy rates of 18–28% per year (17). Barrier methods confer some protection against sexually transmitted diseases.

While long-acting reversible contraceptives are encouraged as first-line contraceptives for all appropriate candidates, including nulliparous women and adolescents (17), lack of data specific to RMD and variability in clinical situations, values, and preferences may affect a patient's choice. Clinical factors that affect appropriateness of various contraceptive methods include diagnosis and activity of SLE, presence of aPL, osteoporosis, and some potentially interacting medications (see Special RMD Situations below and Supplementary Appendix 10, on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). "Hormonal contraceptives" refers to any contraception containing a hormone, including estrogen-progestin contraceptives and progestin-only contraceptives. The term "fertile women" refers to women of reproductive age who do not have documented menopause, hysterectomy, or permanent sterilization (i.e., women who may become pregnant).

In fertile women with RMD who have neither SLE nor positive aPL, we strongly recommend use of effective contraceptives (i.e., hormonal contraceptives or IUDs) over less effective options or no contraception; among effective methods, we conditionally recommend the highly effective IUDs or subdermal progestin implant (long-acting reversible contraceptives) because they have the lowest failure rates.

We strongly recommend discussing use of emergency contraception with all patients, including those with SLE or positive aPL, because risks of emergency contraception are low compared to those of unplanned pregnancy.

Levonorgestrel, the over-the-counter option, is widely available and has no medical contraindications to use, including thrombophilia (18).

SLE patients. Controlled studies of estrogen-progestin contraceptives in SLE have enrolled only women with stable, low disease activity; they specifically excluded those with high disease activity and history of thrombosis (19,20). Prospective studies (evidence level moderate) in patients with stable SLE showed no increased risk of flare related to estrogen-progestin pills (19,20), and there are no data suggesting increased SLE flare risk with progestin-only pills or copper IUDs (20,21).

In SLE patients with stable or low disease activity who are not positive for aPL, we strongly recommend use of effective contraceptives (i.e., hormonal contraceptives or IUDs) over less effective options or no contraception, and we conditionally recommend the highly effective IUDs or subdermal progestin implant because they have the lowest failure rates.

We conditionally recommend *against* use of the transdermal estrogen-progestin patch in patients with SLE.

Although not directly studied in SLE patients, the transdermal estrogen-progestin patch results in greater estrogen exposure than do oral or transvaginal methods (22,23), raising concern regarding potential increased risk of flare or thrombosis.

We strongly recommend progestin-only or IUD contraceptives over combined estrogen-progestin contraception in SLE patients with moderate or severe disease activity, including nephritis, because estrogen-containing contraceptives have not been studied in SLE patients with moderate or severe disease activity.

Antiphospholipid antibody–positive patients. Presence of aPL, with or without history of clinical complications, is a contraindication to use of estrogen-containing contraceptives due the potential further increase in thrombosis risk.

We strongly recommend *against* combined estrogen-progestin contraceptives in women with positive aPL because estrogen increases risk of thromboembolism.

We strongly recommend IUDs (levonorgestrel or copper) or the progestin-only pill in women with positive aPL.

In aPL-positive patients, we do not recommend DMPA due to concern regarding thrombogenicity. We do not comment on the relatively new progestin implant due to lack of data.

The risk of venous thromboembolism (VTE) in healthy women taking combined estrogen-progestin contraceptives is 36 times higher than the baseline annual risk of 1/10,000 women (24). Although whether there is any increase in thrombosis risk with progestin-only contraception is debated, progestin-only methods are widely accepted as a lower-risk option in patients for whom estrogens are contraindicated but who still need effective contraception (18,25,26). The specific progestin and its serum level affect thrombosis risk: in healthy women taking estrogen-progestin contraceptive pills that vary progestin type but not estrogen, VTE risk odds ratios range from 2.2 to 6.6 (24). However, VTE risk in healthy women using either the progestin-only pill or the progestin IUD is not increased, with relative risks (RRs) of 0.90 (95% confidence interval [95% CI] 0.57–1.45) and 0.61 (95% CI 0.24–1.53), respectively (27). Furthermore, thrombosis frequency does not increase when progestin (levonorgestrel) IUDs are used in non-RMD patients with increased (non–aPL-associated) thrombosis risk (27–29). VTE data on the newer progestin (etonogestrel) subdermal implant are inadequate to permit recommendations (the prior progestin implant containing levonorgestrel is no longer available in the US). Very limited data on non-RMD patients suggest that injectable DMPA imparts a higher VTE risk than do other progestin-only contraceptives (RR 2.67 [95% CI1.29–5.53]), similar to that with oral estrogen-progestin contraceptives (27). For this reason, we do not include DMPA among the progestin contraceptives recommended for use in patients with positive aPL.

The copper IUD is a highly effective alternative that does not increase risk of VTE, but it may increase menstrual bleeding and cramping for several months after insertion. Progestin IUDs may decrease these symptoms (30), a potential benefit for patients receiving anticoagulation therapy.

We suggest the progestin-only pill (which is an effective, but not highly effective, contraceptive) as a low-risk alternative for patients who are unable or unwilling to use an IUD. The lack of data specific to aPL-positive patients using the progestin-only pill or IUD must be weighed against the risk of pregnancy-related VTE in the general population, which is >10 times that seen with estrogen-progestin contraceptive use. Pregnancy-related thrombosis risk in aPL-positive patients is not well quantified, but VTE risk is 197/10,000 women-years for pregnant patients with a single prothrombotic mutation and 776/10,000 women-years (31) if there are multiple prothrombotic mutations.

Other special RMD situations. Factors other than diagnosis of SLE or presence of aPL may influence the choice of contraception in women with RMD. These include use of medications and presence or risk of osteoporosis. Immunosuppressive therapy does not preclude use of any contraceptive method, but there is concern that mycophenolate-containing medications may interfere with hormonal contraceptive efficacy.

Since IUDs are the most effective contraceptive options, we strongly recommend the IUD (copper or progestin) for women with RMD who are receiving immunosuppressive therapy, despite hypothetical infection risk.

IUD-associated infection risk in RMD patients receiving immunosuppressive therapy has not been specifically studied, but studies in women with HIV show no increase (32), and IUDs are recommended for all solid organ transplant patients, including adolescents (33,34). In one arm of an SLE contraceptive trial a copper IUD was used; although the number of patients receiving immunosuppressive agents was not reported, there were no cases of pelvic inflammatory disease (20).

In women with RMD who are at increased risk for osteoporosis from glucocorticoid use or underlying disease, we conditionally recommend against using DMPA as a long-term contraceptive because data suggest that bone mineral density declines by up to 7.5% over 2 years of use in a healthy population (35).

Although there are no published data suggesting increased fracture risk, the American College of Obstetricians and Gynecologists recommends caution regarding DMPA use in women with or at increased risk for osteoporosis (17).

We conditionally recommend that women with RMD taking mycophenolate mofetil/mycophenolic acid (MMF) use an IUD alone or 2 other methods of contraception together, because MMF may reduce serum estrogen and progesterone levels (in turn reducing the efficacy of oral contraceptives).

The Mycophenolate Risk Evaluation and Mitigation Strategy program suggests use of an IUD alone (copper or progestin is not specified), or an estrogen-progestin contraceptive or the progestin implant together with a barrier contraceptive (36). It is not known whether these medications reduce efficacy of progestin IUDs, which contain varying amounts of hormone and have a largely

intrauterine effect. Other recommendations vary: while the package insert states that MMF may reduce effectiveness of oral contraceptives and use of additional barrier contraceptive methods is recommended (37), the European Medicine Agency recently updated recommendations regarding use of contraception for women taking MMF to state that "two forms of contraception are preferred but no longer mandatory"(38). Voting Panel members disagreed on the need to use additional contraceptive measures. As befits a conditional recommendation, clinicians should be aware of and discuss this hypothetical risk with their patients.

Assisted reproductive technology

Supplementary Appendix 7, Table B (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents the ART recommendations with strength of supporting evidence; detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 9 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Figure 2 details the ART decision-making process.

While fertility is typically normal in women with RMD (who have not been treated with cyclophosphamide [CYC]), it decreases with age, and ART may be needed by some RMD patients. ART techniques include ovarian stimulation, which elevates estrogen levels, IVF, and embryo transfer. Ovarian stimulation cycles for IVF generally require more aggressive stimulation than do those for intrauterine insemination; they involve surgical extraction of oocytes and IVF, followed by embryo transfer. Frozen embryo transfer does not usually require ovarian stimulation.

As is the case with any underlying significant medical disease, women undertaking ovarian stimulation must be cleared medically by the appropriate specialist. Similarly, women with APS, thrombotic or otherwise, should be cleared medically by their rheumatologist. The rheumatologist should consult with the reproductive endocrinology and infertility specialist regarding adjustments to the ovarian stimulation protocol in order to minimize the risk to the patient. Women with these underlying conditions who undergo fertility therapy should do so only in centers where the appropriate expertise is readily available.

We strongly recommend proceeding with ART if needed in women with uncomplicated RMD who are receiving pregnancy-compatible medications, whose disease is stable/quiescent, and who are negative for aPL.

Compared to the benefit of a successful pregnancy, the risk of ART for subfertile patients with RMD is low; nonetheless,

Treat with therapeutic LMWH/UH during ART procedures [26A]

Figure 2. Recommendations for use of assisted reproductive technology (ART) in women with rheumatic and musculoskeletal disease (RMD). CYC = cyclophosphamide; aPL = antiphospholipid antibody (persistent moderate-to-high–titer anticardiolipin or anti–β_2-glycoprotein I antibody or persistent positive lupus anticoagulant); APS = antiphospholipid syndrome (obstetric and/or thrombotic); obstetric APS (OB APS) = patients meeting laboratory criteria for APS and having prior consistent pregnancy complications (≥3 consecutive losses prior to 10 weeks' gestation, fetal loss at or after 10 weeks' gestation, or delivery at <34 weeks due to preeclampsia, intrauterine growth restriction, or fetal distress) and with no history of thrombosis; thrombotic APS = patients meeting laboratory criteria for APS and having a prior thrombotic event (arterial or venous), regardless of whether they have had obstetric complications; LMWH = low molecular weight heparin; UH = unfractionated heparin.

risks associated with ART, especially thrombosis and lupus flare (39,40), should be discussed with patients. The level of evidence specific to RMD patients is very low (41,42), but evidence supports the safety of ART in a general population (43,44).

SLE patients. Data on IVF cycles in RMD patients are limited; however, the intended outcome of IVF, pregnancy, may be adversely affected by the presence of active RMD. In addition, there is concern that flare in SLE patients might be worsened in the setting of elevated estrogen levels.

We strongly recommend deferring ART procedures in patients with any RMD while disease is moderately or severely active; this recommendation is based on extrapolated evidence that RMD disease activity increases pregnancy risks.

For pregnancy planning, 6 months of stable inactive or low-level disease is most often suggested, but individual clinical factors may influence this decision. In patients with SLE, there is theoretical concern that ovarian stimulation with elevated estrogen levels may worsen active disease.

We conditionally recommend *against* an empiric dosage increase of prednisone during ART procedures in patients with SLE; instead, we suggest monitoring the patient carefully and treating for flare if it occurs.

No studies have evaluated prescription of prophylactic prednisone to prevent SLE flare during ART.

Antiphospholipid antibody–positive patients. Patients who are positive for aPL are at increased risk for thrombosis. Most reports of aPL-positive patients undergoing IVF describe the use of empiric prophylactic anticoagulation due to concern regarding further increased risk of potentially life-threatening thrombosis from elevated estrogen levels during ovarian stimulation.

In subfertile patients with RMD who desire pregnancy, have stable/quiescent disease, and have asymptomatic positive aPL, OB APS, or treated thrombotic APS, we conditionally recommend ART with anticoagulation, as described below.

We conditionally recommend prophylactic anticoagulation therapy with heparin or low molecular weight heparin in asymptomatic aPL-positive patients during ART procedures (41,42).

The increased risk of organ- or life-threatening thrombosis due to high estrogen levels greatly outweighs the low risk of bleeding or other complications of unfractionated heparin or low molecular weight heparin (LMWH).

We strongly recommend prophylactic anticoagulation with heparin or LMWH in women with OB APS, and we strongly recommend therapeutic anticoagulation in women with thrombotic APS, during ART procedures.

The strength of these recommendations rests on the severity of the risk of organ- or life-threatening thrombosis during ovarian stimulation. An added risk for thrombosis is ovarian hyperstimulation syndrome, an important, uncommon complication consisting of capillary leak syndrome (with pleural effusion and ascites) and, in severe cases, arterial and venous thrombosis and renal failure (43). Underlying thrombophilia increases the risk of severe ovarian hyperstimulation syndrome (44). While there are few data to guide prophylactic anticoagulation in aPL-positive patients, thromboprophylaxis is recommended to prevent thrombotic complications of moderate-to-severe ovarian hyperstimulation syndrome, as it is for patients with known inherited or acquired thrombophilia (45,46). Reports of thrombosis in aPL-positive patients undergoing IVF are uncommon, but most reported patients received empiric anticoagulation (41,42). In a recent series, 2 of 4 reported thromboses occurred in women who, on their own decision, discontinued LMWH after oocyte retrieval (41).

LMWH is used most commonly. Prophylactic dosing of enoxaparin is usually 40 mg daily, started at the beginning of ovarian stimulation, withheld 24–36 hours prior to oocyte retrieval, and resumed following retrieval. Optimal duration of prophylactic LMWH for asymptomatic aPL-positive patients undergoing ovarian stimulation has not been studied; this is a decision best made in consultation with the reproductive endocrinology and infertility specialist. The treatment is often continued until estrogen levels return to near-physiologic levels if no pregnancy occurs. Patients with OB APS will continue therapy throughout pregnancy. Aspirin is not commonly used prior to oocyte retrieval (it will be started after retrieval if indicated) given concern that its prolonged action may increase bleeding risk at the time of the retrieval. Patients receiving regular anticoagulation therapy with vitamin K antagonists for thrombotic APS should transition to therapeutic-dose LMWH for ART (usually enoxaparin 1 mg/kg subcutaneously every 12 hours), with this treatment withheld for retrieval and resumed subsequently, to continue throughout pregnancy. Since ovarian stimulation protocols vary, discussion with the reproductive endocrinology and infertility specialist is appropriate. In addition to anticoagulation, patients at risk for thrombosis or ovarian hyperstimulation syndrome may benefit from ovarian stimulation protocols that yield lower peak serum estrogen levels, such as those incorporating aromatase inhibitors (47).

Embryo and oocyte cryopreservation. Embryo and oocyte cryopreservation are good options to preserve fertility in patients whose condition is stable enough for them to undergo ovarian stimulation but who are either not able or not ready to pursue pregnancy at the time of stimulation. A carefully monitored ovarian

stimulation/IVF cycle followed by embryo transfer to a surrogate is an option, if available, for patients with severe disease-related damage who desire a biologic child and are able to undergo ovarian stimulation and oocyte retrieval, but cannot safely undergo pregnancy.

We strongly recommend continuation of necessary immunosuppressive and/or biologic therapies (except CYC, which directly impacts maturing follicles) in treated patients whose condition is stable, when the purpose of ovarian stimulation is oocyte retrieval for oocyte or embryo cryopreservation.

This includes continuation of mycophenolate or methotrexate (MTX). There is an anticipated risk of uncontrolled disease from withdrawal of effective medication. However, there are no published data that directly address oocyte retrieval during treatment with most immunosuppressive or biologic therapies other than CYC.

Fertility preservation with cyclophosphamide

Supplementary Appendix 7, Table C (on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents the formal recommendations regarding fertility preservation with CYC treatment and strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 9 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract).

Fertility preservation in women with RMD treated with CYC. Although CYC is used less frequently than in the past due to availability of alternative treatments, it remains a mainstay of therapy for severe or life-threatening RMD. Ovarian insufficiency is a potential long-term complication of monthly intravenous CYC therapy. Hormonal co-therapy during the course of CYC is suggested to reduce risk of ovarian insufficiency.

To prevent inducing primary ovarian insufficiency in premenopausal women with RMD receiving monthly intravenous CYC, we conditionally recommend monthly gonadotropin-releasing hormone agonist co-therapy.

Ovarian insufficiency risk with CYC treatment depends on patient age and cumulative monthly CYC dose (48); measures of ovarian function remained stable during treatment according to the Euro-Lupus protocol (49). The recommendation of gonadotropin-releasing hormone agonist therapy for ovarian protection during monthly CYC therapy is based on evidence supporting benefit in early breast cancer (50,51); evidence more specific to RMD patients is less robust but positive, with limited clinical trials of gonadotropin-releasing hormone agonist (usually leuprolide acetate) that included patients with SLE and other RMD populations and used a number of different outcome measures (52–56).

Thus far, studies have addressed gonadotropin-releasing hormone agonist co-therapy only in CYC-treated RMD patients who receive CYC monthly by intravenous administration. Acknowledging this lack of data on oral CYC–treated patients, it is reasonable to consider gonadotropin-releasing hormone agonist use for these patients. Theoretically, gonadotropin-releasing hormone agonist co-therapy may not be necessary for patients receiving the lower cumulative CYC dose in the Euro-Lupus regimen (49). Expense including insurance coverage issues and difficulty coordinating administration (preferred timing is 10–14 days prior to CYC administration) may impact the ability to administer gonadotropin-releasing hormone agonist for the first CYC infusion, especially in the setting of urgent need for therapy.

Fertility preservation in men with RMD treated with CYC. CYC may cause infertility and long-term gonadal damage in treated men. Options for fertility preservation should be presented to male patients in whom CYC therapy is required.

We conditionally recommend *against* testosterone co-therapy in men with RMD receiving CYC, as it does not preserve fertility in men undergoing chemotherapy for malignancy (57).

Because sperm cryopreservation prior to treatment preserves a man's ability to conceive a healthy child, we strongly suggest sperm cryopreservation as good practice for CYC-treated men who desire it.

We acknowledge the difficulty of coordinating sperm banking when CYC therapy is urgently indicated. Because CYC causes the most damage to the postmeiosis spermatids and sperm developing during therapy have the highest degree of genetic damage (58), sperm should be collected prior to CYC treatment. If sperm is collected after CYC treatment, urologists recommend waiting a minimum of 3 months after completion of therapy (59).

Menopause and hormone replacement therapy

Supplementary Appendix 7, Table D (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal recommendations regarding menopause and HRT with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 9 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Figure 3 details the HRT decision-making process. In this guideline, postmenopausal women include women with surgically induced menopause.

Current population recommendations (60–62) suggest limiting HRT use in healthy postmenopausal women and using the lowest dose that alleviates symptoms for the minimum time necessary. Studies of long-term HRT show that risks, including stroke and breast cancer, outweigh benefits (63). Risks of HRT

Figure 3. Recommendations and good practice statements (GPS) for hormone replacement therapy (HRT) use in postmenopausal women with rheumatic and musculoskeletal disease (RMD). SLE = systemic lupus erythematosus; aPL = antiphospholipid antibody (persistent moderate-to-high–titer anticardiolipin or anti–β_2-glycoprotein I antibody or persistent positive lupus anticoagulant); APS = antiphospholipid syndrome (obstetric and/or thrombotic); PICO = population, intervention, comparator, outcomes.

depend on the type, dose, route of administration, duration of use, and timing of initiation. Benefit-risk balance is most favorable for severe vasomotor symptoms in women ≤60 years old or within 10 years of menopause onset (61).

Vasomotor symptoms, as defined by the North American Menopause Society, include hot flashes and night sweats. Hot flashes are recurrent, transient episodes of flushing, perspiration, and a sensation ranging from warmth to intense heat on the upper body and face, sometimes followed by chills. Night sweats are hot flashes that occur with perspiration during sleep (64). General contraindications to use of HRT include history of breast cancer, coronary heart disease, previous venous thromboembolic event or stroke, or active liver disease.

We strongly suggest as good practice the use of HRT in postmenopausal women with RMD without SLE or positive aPL who have severe vasomotor symptoms, have no contraindications, and desire treatment with HRT.

SLE patients. Use of HRT in symptomatic postmenopausal SLE patients may raise concerns regarding increased risk of flare and/or thrombosis; however, HRT use in aPL-negative women with quiescent SLE may be considered.

In SLE patients without positive aPL who desire HRT due to severe vasomotor symptoms and have no contraindications, we conditionally recommend HRT treatment.

Moderate-quality direct evidence supports use of oral HRT in aPL-negative women with SLE who have stable low-level disease activity and no contraindication to use (65–68), although no studies have directly addressed use of HRT in patients with moderate-to-high disease activity. The recommendation is conditional because there was a small increase in risk of mild-to-moderate (but not severe) lupus flares with use of oral HRT in the Safety of Estrogens in Lupus Erythematosus National Assessment study (65), and because the studies did not include women with active disease.

aPL-positive patients. Estrogen use in aPL-positive patients should be avoided due to the potential increased risk of thrombosis. Data are limited, however, for many clinical situations, and specific recommendations vary in strength for this reason.

In women with asymptomatic aPL, we conditionally recommend *against* treating with HRT.

We strongly recommend *against* use of HRT in women with obstetric and/or thrombotic APS.

We conditionally recommend *against* HRT use in patients with APS who are receiving anticoagulation treatment and in patients with APS who are currently negative for aPL.

We conditionally recommend consideration of HRT, if desired, in women who have a history of positive aPL but are currently testing negative for aPL and have no history of clinical APS.

Risk of VTE may be increased with HRT use in the general population (69,70). Types of estrogen and progestin and route of administration (71–74) affect risk. In the Women's Health Initiative study, VTE risk with oral estrogen-progestin increased 2-fold over placebo (70), and oral HRT in patients with factor V Leiden or prothrombin G20210A mutations increases VTE risk 25-fold compared to mutation-free women not receiving HRT (75,76). In contrast, recent studies show that transdermal estrogen does not increase VTE risk in healthy women (71,74), even those with prothrombotic mutations or high body mass index (75,77). No studies, however, have specifically assessed thrombosis risk with oral or transdermal HRT in women with aPL.

Direct evidence regarding thrombosis risk with HRT in SLE patients with or without aPL is low, as studies have addressed risk of flare in SLE but not thrombosis, and some studies excluded patients with prior thrombosis (65,67). In one study 106 SLE patients, regardless of aPL status but excluding those with recent thrombosis, were randomized to receive oral estrogen-progestin HRT or placebo. Approximately one-third of the patients in each group had some degree of positivity for aPL (level unreported) (78). During 24 months of follow-up 3 thrombotic events occurred in the HRT group and 1 in the placebo group, a nonsignificant difference.

Available evidence supports the use, when indicated and desired, of HRT in RMD patients without aPL, including those with SLE (65). Given the demonstrated lower VTE risk with transdermal administration as opposed to oral estrogen-progestin preparations even in women at increased prothrombotic risk (77), it may be reasonable to consider transdermal estrogen as initial therapy.

Pregnancy: general assessment, counseling, and management

Obstetrics-gynecology or maternal-fetal medicine specialists necessarily assume primary medical management of pregnancy in a woman with RMD. An understanding of basic pregnancy physiology is helpful for rheumatologists to identify and treat active disease during pregnancy and coordinate care with obstetric providers.

Pregnancy changes may impact manifestations of RMD. Pregnancy-related increased intravascular volume may worsen already abnormal cardiac or renal function. The expected 50% increase in glomerular filtration rate during pregnancy may worsen preexisting stable proteinuria. Pregnancy-induced hypercoagulability increases RMD-associated thrombosis risk. The calcium demand of fetal bone development and breastfeeding may worsen maternal osteoporosis. In addition, normal pregnancy symptoms such as malar erythema, chloasma gravidarum, anemia, elevated erythrocyte sedimentation, and diffuse arthralgias may falsely mimic symptoms of active RMD. Pregnancy-induced hypertension syndromes (preeclampsia) may be confused with lupus nephritis, scleroderma renal crisis, or vasculitis flare. HELLP syndrome (hemolysis, elevated liver enzymes, and low platelets) or eclampsia may resemble severe disease flare. Distinguishing among these syndromes requires the expertise of rheumatologists and obstetrics-gynecology or maternal-fetal medicine physicians working together.

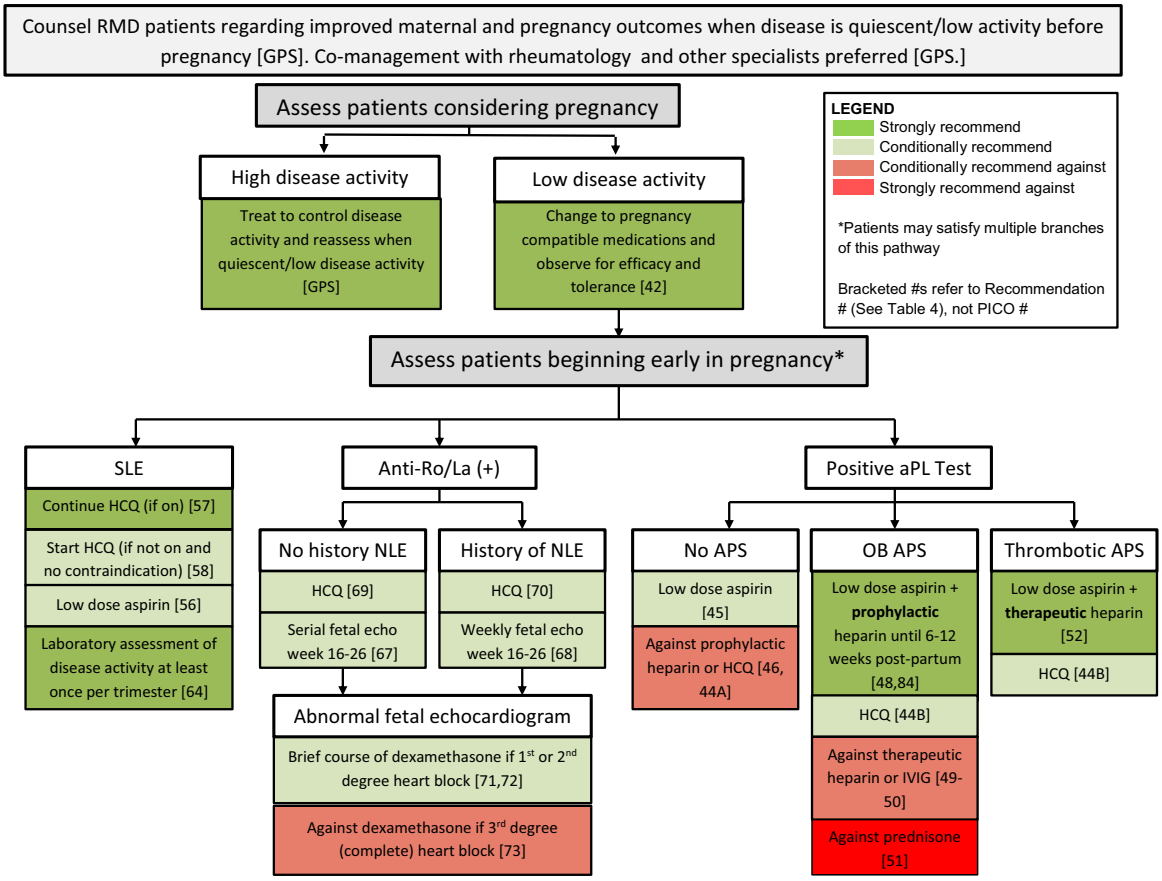
Most information regarding pregnancy management in RMD comes from observational studies, primarily in patients with SLE and APS. There have been very few controlled trials. Data about pregnancies in rare rheumatic diseases usually derive from small case series. For these reasons, many recommendations are conditional, supported by collective experience of the Voting Panel members and patient input. Supplementary Appendix 7, Table E (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal recommendations regarding pregnancy in patients with RMD with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 11 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Figure 4 details the pregnancy management process in patients with RMD. Supplementary Appendix 10 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) provides assessment and management suggestions for specific RMDs.

As standard good practice, we strongly suggest counseling women with RMD who are considering pregnancy regarding the improved maternal and fetal outcomes (based on many studies) associated with entering pregnancy with quiescent/low activity disease (75,77,79–98). As additional good practice, we suggest maintaining concurrent care with specialists in obstetrics-gynecology, maternal-fetal medicine, neonatology, and other specialists as appropriate.

Patient participants expressed a strong desire that their physicians discuss family planning "early and often," including before planning of pregnancy. Discussion with patients should include information on medications and impact of disease activity, autoantibodies, and organ system abnormalities on maternal and fetal health. In rare situations with significant disease-related damage, such as pulmonary arterial hypertension, renal dysfunction, heart failure, or other severe organ damage, pregnancy may be contraindicated due to high risk of maternal morbidity and mortality.

In women with RMD planning pregnancy who are receiving medication that is incompatible with pregnancy, we strongly recommend switching to a pregnancy-compatible medication and observing for sufficient time to assess efficacy and tolerability of the new medication.

There are no data to support a specific period of time for observation with pregnancy-compatible medications. Timing will vary depending on individual clinical factors; in clinical practice this is usually a minimum of several months.



Counsel RMD patients regarding improved maternal and pregnancy outcomes when disease is quiescent/low activity before pregnancy [GPS]. Co-management with rheumatology and other specialists preferred [GPS.]
Assess patients considering pregnancy
High disease activity
Treat to control disease activity and reassess when quiescent/low disease activity [GPS]
Low disease activity

Figure 4. Recommendations and good practice statements (GPS) for pregnancy counseling, assessment, and management in women with rheumatic and musculoskeletal disease (RMD). SLE = systemic lupus erythematosus; HCQ = hydroxychloroquine; NLE = neonatal lupus erythematosus; aPL = antiphospholipid antibody (persistent moderate-to-high–titer anticardiolipin or anti–β_2-glycoprotein I antibody or persistent positive lupus anticoagulant); APS = antiphospholipid syndrome (obstetric and/or thrombotic); obstetric APS (OB APS) = patients meeting laboratory criteria for APS and having prior consistent pregnancy complications (≥3 consecutive losses prior to 10 weeks' gestation, fetal loss at or after 10 weeks' gestation, or delivery at <34 weeks due to preeclampsia, intrauterine growth restriction, or fetal distress) and with no history of thrombosis; thrombotic APS = patients meeting laboratory criteria for APS and having a prior thrombotic event (arterial or venous), regardless of whether they have had obstetric complications; IVIG = intravenous immunoglobulin; PICO = population, intervention, comparator, outcomes.

In women with RMD who are currently pregnant and have active disease that requires medical therapy, we strongly recommend initiating or continuing a pregnancy-compatible steroid-sparing medication, as both active RMD and continuous high-dose glucocorticoid treatment have potential for maternal and fetal harm (99).

Pre-pregnancy or early pregnancy laboratory testing for relevant autoantibodies is recommended. Ascertaining anti-Ro/SSA, anti-La/SSB, and aPL status improves counseling regarding pregnancy and fetal risk.

We strongly recommend testing for anti-Ro/SSA and anti-La/SSB once before or early in pregnancy in women with SLE or SLE-like disorders, Sjögren's syndrome, systemic sclerosis, and rheumatoid arthritis. Given the relative persistence and unchanged titers of these antibodies, we strongly recommend *against* repeating the test during pregnancy.

Patients with scleroderma renal crisis. Most disease-specific recommendations for RMD pregnancy management focus on presence of underlying SLE or positive aPL. One aspect of disease in systemic sclerosis, however, is of particular importance during pregnancy: the development of scleroderma renal crisis. While effective medications are usually contraindicated during pregnancy due to risk of adverse fetal effects, they should be considered in this unusual and life-threatening circumstance.

We strongly recommend use of angiotensin-converting enzyme inhibitor or angiotensin receptor blockade therapy to treat active scleroderma renal crisis in pregnancy, because the risk of maternal or fetal death with untreated disease is higher than the risk associated with use of these medications during pregnancy.

While scleroderma renal crisis is rare in pregnancy (an estimated 2% of scleroderma pregnancies), it can easily be confused

with preeclampsia. Angiotensin-converting enzyme inhibitors can be renal-protective and life saving (100); however, they are contraindicated in the second and third trimesters of pregnancy because of potential oligohydramnios or permanent fetal renal damage (101), and should be considered only for active scleroderma renal crisis.

SLE patients. Supplementary Appendix 7, Table E (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal recommendations for SLE pregnancy management, with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 11 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract).

In women with SLE who are considering pregnancy or are pregnant, we strongly recommend testing for LAC, aCL, and anti-β_2GPI antibodies once before or early in pregnancy, and *against* repeating these tests during pregnancy.

We recommend that all women with SLE take hydroxychloroquine (HCQ) during pregnancy if possible. If a patient is already taking HCQ, we strongly recommend continuing it during pregnancy; if she is not taking HCQ, we conditionally recommend starting it if there is no contraindication.

Many studies support maternal and pregnancy benefit of HCQ and low risk for mother and fetus (84,102–111). Potential contraindications include allergy, adverse side effects, or intolerance.

We conditionally recommend treating SLE patients with low-dose aspirin (81 or 100 mg daily), beginning in the first trimester.

The American College of Obstetricians and Gynecologists and US Protective Health Task Force recommend aspirin 81 mg daily as prophylaxis in all patients at high risk for preeclampsia (97,112–117). Treatment with low-dose aspirin during pregnancy to prevent or delay the onset of gestational hypertensive disease is recommended for those with SLE or APS because of their increased risk and may be considered for women with other RMD diagnoses depending on individual clinical risk factors. Some investigators have used doses of aspirin up to 150 mg daily, but both the American College of Obstetricians and Gynecologists and the U.S. Preventive Services Task Force note that there is a lack of appropriate comparative studies to show the superiority of doses >100 mg per day. Low-dose aspirin is not thought to complicate anesthesia or delivery (112); however, a decision regarding discontinuation prior to delivery should be made by the obstetrician-gynecologist and anesthesiologist according to the patient's specific clinical situation.

Because active disease affects maternal and pregnancy outcome, we strongly suggest, as good practice, monitoring SLE disease activity with clinical history, examination, and laboratory tests at least once per trimester.

Abnormalities in the complete blood cell count, differential cell count, urinalysis results and urinary protein:creatinine ratio, or anti-DNA, C3, or C4 levels may indicate possible SLE flare and/or preeclampsia despite absence of clinical symptoms. Frequency of laboratory monitoring and rheumatology follow-up may vary with an individual patient's clinical status and medications.

Antiphospholipid antibody–positive patients. Pregnancies in patients with positive aPL or APS present specific challenges and may require additional monitoring and therapy. Supplementary Appendix 7, Table F (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal recommendations, with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 11 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract).

Antiphospholipid antibody is a major risk factor for pregnancy loss and other adverse pregnancy outcomes, especially in SLE patients (118). Anti-β_2GPI, aCL, and LAC should all be tested. Among aPLs, LAC conveys the greatest risk for adverse pregnancy outcome in women with or without SLE: the RR for adverse pregnancy outcome with LAC was 12.15 (95% CI 2.92–50.54, $P = 0.0006$) in the PROMISSE (Predictors of Pregnancy Outcome: Biomarkers in APL syndrome and SLE) study (118). Other independent risk factors in aPL-positive women were younger age, history of thrombosis, and SLE.

Antiphospholipid antibody–positive patients without thrombosis or obstetric complications. Asymptomatic aPL-positive patients (those without pregnancy complications or history of thrombosis) are not generally treated with prophylactic therapy to prevent pregnancy loss. However, presence of aPL regardless of clinical history is considered a risk factor for development of preeclampsia.

In pregnant women with positive aPL who do not meet criteria for obstetric or thrombotic APS, we conditionally recommend treating with prophylactic aspirin, 81 or 100 mg daily, during pregnancy as preeclampsia prophylaxis.

Treatment should begin early in pregnancy (before 16 weeks) and continue through delivery.

Patients with obstetric and thrombotic APS. Pregnancy increases the risk of thrombosis due to both hemostatic and anatomic factors. Patients who meet criteria for APS—whether obstetric or thrombotic—should receive therapy with heparin (usually LMWH) to improve pregnancy outcome and/or reduce risk of thrombosis.

We strongly recommend combined low-dose aspirin and prophylactic-dose heparin (usually LMWH) for patients meeting criteria for OB APS (119–126).

This is based on evidence of moderate strength.

In women with OB APS, we further strongly recommend treating with prophylactic-dose anticoagulation for 6–12 weeks post partum (127).

In pregnant women with thrombotic APS, we strongly recommend treating with low-dose aspirin and therapeutic-dose heparin (usually LMWH) throughout pregnancy and post partum.

We conditionally recommend *against* using the combination of prophylactic-dose heparin and low-dose aspirin therapy for patients with positive aPL who do not meet criteria for OB APS.

We appreciate and stress, however, that benefit in individual high-risk circumstances, such as triple-positive aPL or strongly positive LAC results, advanced maternal age, or IVF pregnancy, may outweigh risks of this therapy, and decisions should be made with discussion between physician and patient, weighing potential risks and benefits.

Other therapies for refractory OB APS. Despite improved outcomes with standard therapy with low-dose aspirin and prophylactic heparin/LMWH, additional treatments are needed for patients who do not respond to standard therapy. Intravenous immunoglobuin, low-dose prednisone, increased dose of heparin/LMWH, and HCQ have all been suggested as additional or alternative treatments.

We conditionally recommend *against* treatment with intravenous immunoglobulin or an increased LMWH dose, as these have not been demonstrably helpful in cases of pregnancy loss despite standard therapy with low-dose aspirin and prophylactic heparin or LMWH.

Prophylactic-dose heparin and aspirin therapy for OB APS improves likelihood of live birth, but not necessarily full-term birth. Pregnancy loss occurs, despite treatment, in 25% of OB APS pregnancies. There are no data demonstrating improved outcomes with a higher dose of heparin, and only anecdotal data support the use of intravenous immunoglobulin.

We strongly recommend *against* adding prednisone to prophylactic-dose heparin or LMWH and low-dose aspirin in patients in whom standard therapy has been unsuccessful, since there are no controlled studies demonstrating a benefit.

We acknowledge, however, that this recommendation is based on a lack of compelling data rather than data showing no clear benefit, and also that potential risk with this therapy is likely to be strongly affected by daily dosage, with higher doses imparting greater risk of side effects.

We conditionally recommend the addition of HCQ to prophylactic-dose heparin or LMWH and low-dose aspirin therapy for patients with primary APS.

Recent small studies of APS pregnancies suggest that HCQ may decrease complications (111).

In pregnant women with positive aPL who do not meet criteria for APS and do not have another indication for the drug (such as SLE), we conditionally recommend *against* treating with prophylactic HCQ.

As with any unproven treatment, this therapy may be considered in specific circumstances, depending on a patient's values and preferences and after a discussion about risks and benefits.

Anti-Ro/SSA and/or anti-La/SSB antibodies in pregnancy. Neonatal lupus erythematosus (NLE) describes several fetal and infant manifestations caused by or associated with maternal anti-Ro/SSA (commonly) and anti-La/SSB autoantibodies. While isolated anti-La/SSB rarely imposes risk, when combined with anti-Ro/SSA, La/SSB antibodies may increase fetal risk (128). Prospective studies of infants born to women with anti-Ro/SSA and/or anti-La/SSB antibodies show that ~10% develop an NLE rash, 20% transient cytopenias, and 30% mild transient transaminitis (estimates vary widely between reports). These complications are short-lived and spontaneously resolve as the child's maternal antibodies disappear (129).

Complete (third-degree) heart block (CHB) occurs in ~2% of pregnancies of women with anti-Ro/SSA and/or anti-La/SSB antibodies who have not had a prior infant with NLE, and in 13–18% of pregnancies of women with a prior infant who had either cutaneous or cardiac NLE (130). Low-titer antibodies are probably not associated with the same risk of CHB as higher titers (131). CHB rarely occurs after week 26. It is irreversible, and management transfers to pediatric cardiologists. Approximately 20% of children with CHB die in utero or in the first year of life; more than half will need a pacemaker (128).

Supplementary Appendix 7, Table G (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal recommendations regarding pregnancy in women with anti-Ro/SSA and/or anti-La/SSB antibodies, with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 11 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract).

In pregnant women with anti-Ro/SSA and/or anti-La/SSB antibodies but no history of an infant with CHB or NLE, we conditionally recommend serial fetal echocardiography (less frequent than weekly; interval not determined) starting between 16 and 18 weeks and continuing

through week 26. For women with a prior infant with CHB or other NLE we conditionally recommend fetal echocardiography weekly, starting at week 16–18 and continuing through week 26.

Recommendations regarding monitoring for and treatment of CHB in women with anti-Ro/SSA and/or anti-La/SSB are all conditional. Given the rarity of CHB, large case series are not available; most studies are retrospective and not randomized. An argument against screening includes the risk of identification and treatment of artifacts that do not impact offspring health, thus exposing both fetus and mother to long-term side effects of dexamethasone; this risk must be balanced against the potentially devastating impact of CHB. All discussions should acknowledge the limited data and consider the patient's values and preferences.

We conditionally recommend treating all women who are positive for anti-Ro/SSA and/or anti-La/SSB antibodies with HCQ during pregnancy.

This is based on early and limited data and the low risk profile of HCQ. Retrospective studies demonstrate that in pregnant women with a prior child with cardiac NLE who take HCQ, there is a lower risk of the current fetus developing CHB (132).

For pregnant women with anti-Ro/SSA and/or anti-La/SSB antibodies and fetal first- or second-degree heart block shown on echocardiography, we conditionally recommend treatment with oral dexamethasone 4 mg daily. If CHB (without other cardiac inflammation) is present, we conditionally recommend *against* treating with dexamethasone.

Fluorinated glucocorticoids, such as dexamethasone and betamethasone, cross the placenta; low-to-moderate–dose nonfluorinated glucocorticoids, such as prednisone and prednisolone, are largely metabolized before they reach the fetus. Whether dexamethasone given for fetal first- or second-degree heart block changes outcome is a matter of controversy. Treatment should be limited to several weeks, depending on response, because of the risk of irreversible fetal and maternal toxicity. Whether dexamethasone improves long-term survival for a fetus with CHB is controversial (133,134), but recent analyses do not support its use (135).

Medication use

Paternal medication use. Supplementary Appendix 7, Table H (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents best practice statements and recommendations regarding paternal medication use in men with RMD, with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 12 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Table 2 summarizes recommendations for paternal medication use.

Medication issues differ between men with RMD who are planning to father a pregnancy and those whose sexual partner is pregnant. Pre-conception, the concerns are potential effects on male fertility and medication-associated teratogenicity. There are few published data addressing these potential effects of medications for RMD. A decision to stop a medication must be weighed against the impact it may have on paternal disease activity.

When the man's partner is pregnant, the concern is whether his medication is present in seminal fluid and can transfer through vaginal mucosa, cross the placenta, and be teratogenic. In fact, post-conception exposure of the embryo or fetus is likely minimal,

Table 2. Recommendations regarding medication use for men with rheumatic and musculoskeletal disease who are planning to father a child

Strongly recommend continuing	Conditionally recommend continuing	Strongly recommend discontinuing	Conditionally recommend discontinuing	Unable to make a recommendation due to limited data
Azathioprine/ 6-mercaptopurine Colchicine Hydroxychloroquine Tumor necrosis factor inhibitors (all)	Anakinra Cyclooxygenase 2 inhibitors Cyclosporine Leflunomide Methotrexate Mycophenolate mofetil Mycophenolic acid Nonsteroidal anti-inflammatory drugs Rituximab Sulfasalazine *(semen analysis if delayed conception)* Tacrolimus	Cyclophosphamide *(discontinue 12 weeks prior to attempted conception)*	Thalidomide *(discontinue 4 weeks prior to attempted conception)*	Abatacept Apremilast Baricitinib Belimumab Secukinumab Tocilizumab Tofacitinib Ustekinumab

Table 3. Maternal medication use: overview of medication use before and during pregnancy, and during breastfeeding

Medication	Pre-conception	During pregnancy	Breastfeeding
Conventional medications			
Hydroxychloroquine	++	++	++
Sulfasalazine	++	++	++
Colchicine	++	++	++
Azathioprine, 6-mercaptopurine	++	++	+ Low transfer
Prednisone	+ Taper to <20 mg/day by adding pregnancy-compatible immunosuppressants	+ Taper to <20 mg/day by adding pregnancy-compatible immunosuppressants	+ After a dose of >20 mg, delay breastfeeding for 4 hours
Cyclosporine, tacrolimus	+ Monitor blood pressure	+ Monitor blood pressure	+ Low transfer
Nonsteroidal antiinflammatory drugs (cyclooxygenase 2 inhibitors not preferred)	+ Discontinue if the woman is having difficulty conceiving	+ Continue in first and second trimesters; discontinue in third trimester	+ Ibuprofen preferred
Tumor necrosis factor inhibitors (tumor necrosis factor inhibitors are considered compatible with pregnancy)			
Certolizumab	++	++	++
Infliximab, etanercept, adalimumab, golimumab	+ Continue through conception	+ Continue in first and second trimesters; discontinue in third trimester several half-lives prior to delivery	++
Rituximab	+ Discontinue at conception	+ Life-/organ-threatening disease	++
Other biologics (limited safety data; limited transfer in early pregnancy but high transfer in second half of pregnancy)			
Anakinra, belimumab, abatacept, tocilizumab, secukinumab, ustekinumab	+ Discontinue at conception	× Discontinue during pregnancy	+ Expect minimal transfer due to large molecular size, but no available data
Not compatible with pregnancy			
Methotrexate	×× Stop 1–3 months prior to conception	×× Stop and give folic acid 5 mg/day	× Limited data suggest low transfer
Leflunomide	×× Cholestyramine washout if detectable levels	×× Stop and give cholestyramine washout	××
Mycophenolate mofetil and mycophenolic acid	×× Stop >6 weeks prior to conception to assess disease stability	××	××
Cyclophosphamide	×× Stop 3 months prior to conception	+ Life-/organ-threatening disease in second and third trimesters	××
Thalidomide	×× Stop 1–3 months prior to conception	××	××
Tofacitinib, apremilast, baricitinib	Unable to determine due to lack of data; small molecular size suggests transfer across the placenta and into breast milk		

++ Strongly recommend

\+ Conditionally recommend

× Conditionally recommend against

×× Strongly recommend against

as seminal concentrations of medications and volumes transferred are small (136). There are no reports of post-conception teratogenesis attributable to medications taken by a man with RMD. When a man's sexual partner is pregnant, reassurance regarding low risk associated with his RMD treatment is generally warranted.

In the absence of adequate data regarding paternal exposure for most medications used for RMD, we developed recommendation statements when 1) at least some data on paternal exposure were available, 2) accumulated clinical experience of paternal exposure could guide the recommendation, or 3) there were no data on paternal exposure, but maternal exposure demonstrates teratogenicity. We do not present recommendations for new medications with no available class-level or drug-specific data.

We strongly recommend *against* use of CYC and thalidomide in men prior to attempting conception.

Paternal use of CYC may impair spermatogenesis or be mutagenic for DNA (137) and should be discontinued 3 months prior to attempting conception. Thalidomide is detectable in seminal fluid and is strongly teratogenic when given to pregnant women (138,139), and should be discontinued at least 1 month prior to attempting conception. The remaining medications are recommended either strongly or conditionally for continuation during peri- and post-conception periods.

In men with RMD who are planning to father a pregnancy, we strongly recommend continuation of HCQ, azathioprine, 6-mercaptopurine, colchicine, and tumor necrosis factor inhibitors (140–142).

In men with RMD who are planning to father a pregnancy, we conditionally recommend, based on a smaller body of evidence, continuing treatment with MTX, MMF, leflunomide, sulfasalazine, calcineurin inhibitors, and nonsteroidal antiinflammatory drugs (NSAIDs) (142–149).

Although the drug label suggests discontinuation of MTX before attempting pregnancy, data show no evidence for mutagenesis or teratogenicity (143–145).

Although sulfasalazine may affect sperm count and quality, there are no data suggesting teratogenicity (146,150), and we conditionally recommend its continuation. If conception does not occur, semen analysis should be considered.

We conditionally recommend continuation of anakinra and rituximab based on limited data (151,152).

Maternal medication use. Supplementary Appendix 7, Tables I (conventional rheumatology medications), J (biologic rheumatology medications), and K (glucocorticoids) (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) present formal best practice statements and recommendations regarding maternal medication use in patients with RMD, with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 12 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). Table 3 summarizes recommendations for maternal medication use.

As standard good practice, we suggest discussing medications well before the patient attempts to conceive; we also suggest discussing pregnancy plans prior to initiating treatment with medications that may affect gonadal function, such as CYC.

There are no published data regarding specific timing for medication discussion, which will vary according to the individual clinical situation, but in general we suggest adequate time to allow for appropriate medication changes and demonstration of tolerability and disease stability, usually a minimum of several months.

MTX, MMF, CYC, and thalidomide are known teratogens. We strongly recommend discontinuation of these within 3 months prior to conception (153–156).

Data regarding timing of discontinuation are conflicting and do not permit more specific recommendations. However, discontinuation within 1 menstrual cycle would represent the minimum, and 3 months the most common, period for discontinuation. In addition to concerns about teratogenicity, it is optimal to allow adequate time for observation of disease stability without medication.

For women treated with leflunomide, we strongly recommend cholestyramine washout if there are detectable serum levels of metabolite prior to or as soon as pregnancy is confirmed. Once metabolite is not detectable in the serum, the risks of pregnancy loss and birth defects are not elevated (157,158).

We conditionally recommend treatment with CYC for life-threatening conditions in the second or third trimester (86).

When potentially teratogenic medications are discontinued prior to pregnancy, we strongly recommend a period of observation without medication or transition to pregnancy-compatible medications to ensure disease stability (as discussed above). In women with inadvertent exposure to teratogenic medications we strongly suggest immediate referral to a maternal-fetal medicine specialist, pregnancy medication specialist, or genetics counselor as standard good practice.

We strongly recommend HCQ, azathioprine/6-mercaptopurine, colchicine, and sulfasalazine, medications commonly used for RMD, as compatible for use throughout pregnancy (104,106,159–161).

We conditionally recommend calcineurin inhibitors (tacrolimus and cyclosporine) and NSAIDs as compatible for use during pregnancy (154).

We conditionally recommend discontinuation of NSAIDs pre-conception if the patient is having difficulty conceiving (and if disease control would not be compromised), due to the possibility of NSAID-induced unruptured follicle syndrome, a cause of subfertility (162).

We strongly recommend *against* use of NSAIDs in the third trimester because of the risk of premature closure of the ductus arteriosus (163).

We conditionally recommend nonselective NSAIDs over cyclooxygenase 2–specific inhibitors in the first 2 trimesters, due to lack of data on cyclooxygenase 2–specific inhibitors.

Nonfluorinated glucocorticoids should be used when needed, but substitution of steroid-sparing pregnancy-compatible immunosuppressive therapy is desirable when high-dose or prolonged use is required.

We conditionally recommend continuing low-dose glucocorticoid treatment (≤10 mg daily of prednisone or nonfluorinated equivalent) during pregnancy if clinically indicated. We strongly recommend tapering higher doses of nonfluorinated glucocorticoids to <20 mg daily of prednisone, adding a pregnancy-compatible glucocorticoid-sparing agent if necessary. Although there are only minimal data regarding prolonged treatment with low-dose glucocorticoids during pregnancy, we conditionally recommend *against* routine administration of stress-dose glucocorticoids at the time of vaginal delivery, but conditionally do recommend such treatment for surgical (cesarean) delivery.

We conditionally recommend continuing tumor necrosis factor inhibitor therapy with infliximab, etanercept, adalimumab, or golimumab prior to and during pregnancy (164,165). The tumor necrosis factor inhibitor certolizumab does not contain an Fc chain and thus has minimal placental transfer (166). We strongly recommend continuation of certolizumab therapy prior to and during pregnancy.

Placental transfer and fetal exposure for most biologic therapies vary with gestational stage. The majority of RMD biologic therapies contain an Fc IgG1 construct that does not cross into the fetal circulation in significant concentrations until the second trimester (167). Use of the tumor necrosis factor (TNF) inhibitors that include an IgG1 Fc construct during the third trimester (infliximab, etanercept, adalimumab, and golimumab) results in high levels of placental transfer and significant drug levels in the neonate. A modest amount of evidence suggests that these TNF inhibitors cause no adverse effects, especially in the first trimester. There was extensive Voting Panel discussion regarding if, and when, these medications should be discontinued prior to delivery. The Voting Panel agreed that if the patient's disease is under good control, these medications may be discontinued in the third trimester. While there is a paucity of safety data, continuing TNF inhibitors through delivery if the patient's disease is active can be considered, with the understanding that the neonate will have significant serum levels of drug for a period of time.

There are limited data on the compatibility of other biologics with pregnancy. Given that these agents likely do not cross the placenta until the second trimester, the panel conditionally recommends that non–TNF inhibitor IgG-based molecules are compatible in the periconception period but should be discontinued during pregnancy (i.e. at the time of the first positive pregnancy test result).

We conditionally recommend continuing treatment with anakinra, belimumab, abatacept, tocilizumab, secukinumab, and ustekinumab while a woman is trying to conceive, but discontinuing once she is found to be pregnant.

If disease cannot be controlled with medications considered compatible with pregnancy, the physician and patient should discuss and weigh the possible risks from these medications versus the risks of uncontrolled disease during pregnancy.

We conditionally recommend continuing treatment with rituximab while a woman is trying to conceive, and we conditionally recommend continuing rituximab during pregnancy if severe life- or organ-threatening maternal disease so warrants.

Dosing in the second half of pregnancy puts the fetus at high risk of having minimal B cells at delivery (168).

There is no available evidence regarding use or safety of the new small-molecule agents, tofacitinib, baricitinib, and apremilast, during pregnancy. The Voting Panel elected not to offer recommendations regarding these drugs. It should be noted, however, that small molecules are likely to pass through the placenta.

Medication use during breastfeeding. The benefits of breastfeeding are numerous (169–175); the American Academy of Pediatrics recommends exclusive breastfeeding for the first 6 months and continued breastfeeding until 1 year (9). Because women with RMD may experience disease flare post partum and require treatment, it is important to balance benefits of disease control with risk of infant exposure through breast milk.

Infant serum levels of drugs ingested by the mother depend on multiple variables and are a function of drug concentration in breast milk, quantity of breast milk ingested, and drug absorption through the infant's gastrointestinal tract. Premature infants

Table 4. Reproductive health care in patients with RMD: concise recommendation summary*

Topic	Recommendation	Strength
Contraception		
All RMD	Contraception/pregnancy discussion early and regularly; choose contraception based on safety, efficacy, and patient preference	GPS
	Use barrier methods if unable to use other methods	GPS
	Use emergency contraception if necessary [6]	Strong
	Women receiving immunosuppressive medications: Use IUD if desired [7]	Strong
	Women at risk for osteoporosis: *Avoid* DMPA [10]	Conditional
	Women receiving MMF: Use IUD or 2 other methods together [11]	Conditional
	RMD without SLE or aPL: Use highly effective or effective methods† [1]	Strong
	Highly effective methods preferred to effective methods [1A]	Conditional
SLE	SLE with negative aPL and low/stable disease activity: Use highly effective or effective methods† [2]	Strong
	Highly effective methods preferred to effective methods [2A]	Conditional
	Avoid transdermal estrogen-progestin patch [2B]	Conditional
	SLE with negative aPL and moderate-to-high disease activity: Use progestin-only contraceptives or IUD [2C]	Strong
Positive aPL	Do *not* use combined estrogen-progestin contraceptives [3]; use IUD or progestin-only pill [4]	Strong
Assisted reproductive technology		
All RMD	Stable disease and negative aPL: Proceed with assisted reproductive technology:	
	IVF if pregnancy-compatible medications [24]	Strong
	Oocyte cryopreservation: Continue medications except CYC [28]	Strong
	Active disease: Defer assisted reproductive technology until disease is stable/quiescent [27]	Strong
SLE	Active SLE: Defer assisted reproductive technology until disease is stable/quiescent [27]	Strong
	Do *not* treat with prophylactic prednisone [29]	Conditional
Positive aPL	No prior thromboses or OB APS: Prophylactic heparin or LMWH [25A]	Conditional
	No prior thromboses but history of OB APS: Prophylactic heparin or LMWH [25A2]	Strong
	Prior thromboses: Therapeutic heparin or LMWH [26A]	Strong
Fertility preservation	Women: Use gonadotropin-releasing hormone agonist therapy during IV CYC treatment [31]	Conditional
	Men: Sperm cryopreservation pre–CYC treatment	GPS
	Do *not* use gonadotropin-releasing hormone agonist therapy [35]	Conditional
Menopause/hormone replacement therapy		
All RMD	RMD without SLE or aPL: Treat with hormone replacement therapy if indicated‡	GPS
SLE	SLE and negative aPL: Treat with hormone replacement therapy if indicated‡ [79]	Conditional
Positive aPL	If no prior thrombosis or OB APS: Do *not* treat with hormone replacement therapy [80]	Conditional
	If current titers negative, treat with hormone replacement therapy if indicated‡ [83]	Conditional
	If prior thrombosis or OB APS and not receiving anticoagulation treatment: Do *not* treat with hormone replacement therapy [81]	Strong
	If current titers negative, do *not* treat with hormone replacement therapy [83A]	Conditional
	If prior thrombosis or OB APS and receiving anticoagulation treatment: Do *not* treat with hormone replacement therapy [82]	Conditional
Pregnancy		
All RMD	Counseling: Outcomes improved with pregnancy planning, stable disease, compatible medications, and co-management by rheumatology and obstetrics-gynecology/maternal-fetal medicine	GPS
	Pre-pregnancy: Change to pregnancy-compatible medication and observe for stability [42]	Strong
	If active disease during pregnancy: Initiate pregnancy-compatible medication [54]	Strong
	If SLE or SLE-like disease, SS, SSc, or RA: Test once (early) for anti-Ro/SSA and anti-La/SSB [60, 62]	Strong
	If SSc and renal crisis during pregnancy: Treat with ACE inhibitor or ARB for life-threatening disease [55]	Strong

(Continued)

Table 4. (*Cont'd*)

Topic	Recommendation	Strength
SLE	SLE or SLE-like disease: Test once (early) for aPL (aCL, anti-β_2GPI, LAC) [59, 61]	Strong
	Continue HCQ during pregnancy [57]	Strong
	If not taking HCQ, start HCQ during pregnancy if no contraindications [58]	Conditional
	Monitor laboratory values at least once per trimester	GPS
	Treat with low-dose aspirin starting in first trimester [56]	Conditional
Positive aPL	Positive aPL only: If no prior thrombosis or OB APS, treat with low-dose aspirin starting in first trimester [45]	Conditional
	Do *not* treat with combination prophylactic heparin or LMWH/low-dose aspirin [46]	Conditional
	Do *not* treat with HCQ [44A]	Conditional
	OB APS: If no thrombosis but meet OB APS criteria, treat with combination prophylactic heparin or LMWH/low-dose aspirin [48]	Strong
	Do *not* treat with combination therapeutic heparin or LMWH/low-dose aspirin [49]	Conditional
	Do *not* treat with addition of IVIG [50]	Conditional
	Do *not* treat with addition of prednisone [51]	Strong
	Treat with addition of HCQ for combination heparin/low-dose aspirin failure [44B]	Conditional
	Treat with prophylactic anticoagulation during post partum period [84]	Strong
	Thrombotic APS: If prior thrombosis (meeting or not meeting OB APS criteria), treat with therapeutic heparin or LMWH/low-dose aspirin [52]	Strong
	Treat with addition of HCQ for therapeutic heparin or LMWH/low-dose aspirin therapy failure [44B]	Conditional
Positive anti-Ro/SSA with or without anti-La/SSB	Treat with HCQ during pregnancy [69, 70]	Conditional
	If no prior history of neonatal lupus: Serial (interval uncertain) fetal echocardiography in weeks 16–26 [67]	Conditional
	If prior history of neonatal lupus: Weekly fetal echocardiography in weeks 16–26 [68]	Conditional
	Abnormal fetal echocardiography: If first- or second-degree heart block, treat with dexamethasone 4 mg daily [71, 72]	Conditional
	If isolated third-degree heart block (and no other cardiac inflammation), do *not* treat with dexamethasone [73]	Conditional
Medication		
Paternal medication	If planning to father a child: Discuss medication use including CYC	GPS
	Discontinue CYC and thalidomide [133, 139]	Strong/conditional
	Continue HCQ, AZA, infliximab, etanercept, adalimumab, golimumab, certolizumab, colchicine [90, 115, 143, 146, 149, 152, 155, 97]	Strong
	Continue leflunomide, MMF, NSAIDs, sulfasalazine, cyclosporine, tacrolimus, anakinra, rituximab [108, 119, 85, 94, 126, 130, 159, 163]	Conditional
Maternal medication	If planning pregnancy: Discuss medication use including CYC	GPS
	If pregnant and exposed to teratogenic medications: Discontinue immediately, pursue counseling	GPS
	Discontinue NSAIDs if difficulty conceiving [86]	Conditional
	Avoid NSAIDs in third trimester [87]	Strong
	Use nonselective rather than COX-2–specific NSAIDs [88]	Conditional
	Discontinue MTX, MMF, thalidomide, CYC prior to conception [102, 120, 140, 134]	Strong
	Use CYC for life-threatening disease only in second and third trimester [136]	Conditional
	Discontinue leflunomide 24 months prior to conception or check serum metabolite levels and treat with cholestyramine washout [109, 110]	Strong
	Continue HCQ, sulfasalazine, AZA, colchicine [91, 95, 116, 98]	Strong
	Continue cyclosporine and tacrolimus [127, 131]	Conditional
	Continue certolizumab [156]	Strong
	Continue infliximab, etanercept, adalimumab, golimumab [144, 147, 150, 153]	Conditional
	Stop when pregnancy confirmed: rituximab, belimumab, anakinra, abatacept, tocilizumab, secukinumab, ustekinumab [164, 169, 160, 173, 177, 181, 185]	Conditional
	Use rituximab for organ- or life-threatening disease during pregnancy [165]	Conditional
	No recommendations for tofacitinib, baricitinib, apremilast due to lack of data [189, 193, 197]	
	Continue regular low-dose prednisone [201]	Conditional

(Continued)

Table 4. (*Cont'd*)

Topic	Recommendation	Strength
	Taper high-dose prednisone with addition of pregnancy-compatible drug if needed [202]	Strong
	Stress-dose steroid at delivery: do *not* treat for vaginal delivery, do treat for cesarean delivery [206, 207]	Conditional
Breastfeeding	Encourage breastfeeding and maintain disease control with compatible medications if possible	GPS
	Compatible medications:	
	HCQ, infliximab, etanercept, adalimumab, golimumab, certolizumab, rituximab [92, 143, 146, 149, 152, 155]	Strong
	NSAIDs, sulfasalazine, colchicine, AZA, cyclosporine, tacrolimus, anakinra, belimumab, abatacept, tocilizumab, secukinumab, ustekinumab [89, 96, 99, 117, 128, 132, 161, 170, 174, 178, 182, 186]	Conditional
	Prednisone or nonfluorinated steroid equivalent <20 mg daily [204]	Strong
	For prednisone ≥20 mg daily, discard breast milk obtained within 4 hours following medication [205]	Strong
	Do *not* treat with leflunomide, MMF, CYC, thalidomide [113, 124, 137, 142]	Strong
	Do *not* treat with MTX [106]	Conditional

* Recommendation numbers, shown in brackets, allow for cross-referencing with supplementary appendices. For more detailed/complete recommendations, see text or Supplementary Appendix 7 (on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract). RMD = rheumatic and musculoskeletal disease; GPS = good practice statement; MMF = mycophenolate mofetil (and mycophenolic acid); SLE = systemic lupus erythematosus; aPL = antiphospholipid antibody, meeting laboratory criteria for antiphospholipid syndrome (APS) (Supplementary Appendix 8, http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract); IVF = in vitro fertilization; CYC = cyclophosphamide; OB APS = APS meeting laboratory criteria and clinical obstetric criteria (Supplementary Appendix 8); LMWH = low molecular weight heparin; IV = intravenous; SS = Sjögren's syndrome; SSc = systemic sclerosis; RA = rheumatoid arthritis; ACE inhibitor = angiotensin-converting enzyme inhibitor; ARB = angiotensin receptor blocker; aCL = anticardiolipin antibody; anti-β_2GPI = anti–β_2-glycoprotein I; LAC = lupus anticoagulant; HCQ = hydroxychloroquine; IVIG = IV immunoglobulin; AZA = azathioprine (and 5-fluorouracil); NSAIDs = nonsteroidal antiinflammatory drugs; COX-2 = cyclooxygenase 2; MTX = methotrexate.
† Highly effective contraceptives are long-acting reversible contraceptives including progestin or copper intrauterine device (IUD) and progestin implant. Effective contraceptives are estrogen-progestin contraceptives (oral, patch, or vaginal ring) and progestin-only (oral, depot medroxyprogesterone acetate [DMPA]).
‡ General indication for hormone replacement therapy: Current recommendations suggest limiting hormone replacement therapy use in healthy postmenopausal women and using the lowest dose that alleviates symptoms for the minimum time necessary. Benefit-risk balance is most favorable for severe vasomotor symptoms in women ≤60 years old or within 10 years of menopause onset (ref. 61).

or those with gastrointestinal disorders may absorb medication differently. Rheumatologists should collaborate with pediatricians when making recommendations (176). Levels of drug in breast milk are routinely expressed as the relative infant dose (infant dose mg/kg/day divided by maternal dose mg/kg/day) and are available in reference publications; a value of <10% is considered safe.

Supplementary Appendix 7, Table L (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract) presents formal best practice statements and recommendations for use of medications during breastfeeding, with strength of supporting evidence. Detailed justifications for strong and conditional recommendations are shown in Supplementary Appendix 12 (http://onlinelibrary.wiley.com/doi/10.1002/art.41191/abstract).

We suggest as standard good practice that women with RMD be encouraged to breastfeed if they so desire and are able to do so. In addition, we suggest that disease control be maintained with lactation-compatible medications and that individualized risks and benefits be reviewed with each patient.

Fortunately, many RMD medications may be initiated or continued during lactation.

We strongly recommend treatment with HCQ, colchicine, sulfasalazine, rituximab, and all TNF inhibitors as compatible with breastfeeding (177–181).

We also recommend prednisone <20 mg daily (or equivalent nonfluorinated glucocorticoid) as compatible with breastfeeding, but strongly recommend that with doses of prednisone ≥20 mg a day (or equivalent), women delay breastfeeding or discard breast milk accumulated in the 4 hours following glucocorticoid administration.

We conditionally recommend treatment with azathioprine/6-mercaptopurine, calcineurin inhibitors, NSAIDs and the non–TNF inhibitor biologic agents (anakinra, rituximab, belimumab, abatacept, tocilizumab, secukinumab, and ustekinumab) as compatible with breastfeeding (182–184).

We strongly recommend *against* use of CYC, leflunomide, MMF, and thalidomide while breastfeeding. We conditionally recommend *against* use of MTX while breastfeeding.

Despite minimal passage of MTX into breast milk, especially with once-weekly dosing, this medication may accumulate in neonatal tissues (185,186).

The Voting Panel declined to vote on the compatibility of new small-molecule agents regarding use during breastfeeding due to absence of data. In theory, however, these medications may transfer into breast milk because of their low molecular weights.

DISCUSSION

Patients' reproductive health concerns are relevant for all practicing rheumatologists. Issues regarding contraception, fertility, pregnancy, lactation, and the offspring's health affect almost every patient across all RMD diagnoses. The importance of this area is highlighted by recent publications that have addressed key elements of reproductive health for some or all RMD patients. The European League Against Rheumatism (EULAR) published recommendations regarding women's health issues in patients with SLE and APS (187), and both EULAR (with points to consider) and the British Society for Rheumatology/British Health Professionals in Rheumatology (with guideline recommendations) addressed use of medications before, during, and after RMD pregnancy (188–190). Here, we address broad reproductive health concerns as well as medication use surrounding pregnancy for all RMD patients, with special attention, when indicated, for patients with specific disorders such as SLE or APS.

Even with the wide spectrum of reproductive issues addressed here (Table 4), this project has important limitations. This guideline was developed, and the literature review conducted, in the adult population. An important future step will be to consider these issues among adolescents, as counseling and care for these patients may differ.

Another important limitation is the inability to include recommendations for uncommon but important clinical situations. Although our mandate was broad, our task was to derive and support our recommendations with available evidence, but many uncommon clinical scenarios have little published data. One such situation that reflects an ongoing research need is the challenge of reproductive health issues specific to transgender individuals, especially regarding hormonal therapies.

A relatively rare but important scenario is the therapeutic termination of pregnancy in patients with life-threatening disease damage or flare. Pregnancy in patients with preexisting severe organ damage carries profound maternal risk. Pulmonary arterial hypertension is associated with a particularly high risk of maternal mortality, estimated at up to 20% even with aggressive therapy (191). Other high-risk scenarios include severe renal insufficiency, cardiomyopathy, or valvular dysfunction. Severe autoimmune disease flare occurring during pregnancy—including diffuse alveolar hemorrhage, active nephritis or vasculitis, or central nervous system inflammation—also carries high risk for maternal morbidity and mortality (55,192–194). In these and other high-risk situations, the option of therapeutic termination of pregnancy may be lifesaving and should be discussed with the patient (195). Decisions regarding pregnancy termination in the setting of teratogenic medication exposure will depend on the specific medication, timing of exposure, and the patient's assessment of the available data; counseling by expert professionals such as maternal-fetal medicine or genetics specialists regarding degree of risk based on specific circumstances is suggested in these cases.

We provide data-derived recommendations for common clinical reproductive health decisions including recent advances in this area and emphasize the need for early involvement of the rheumatologist in reproductive health discussions involving patients with RMD, for instance, the importance of effective contraception. Almost half of pregnancies in the US are unplanned (196). In RMD patients unplanned pregnancies carry greater risk than do planned pregnancies in periods of low disease activity treated with compatible medications. Whether considering pregnancy or not, patients should know maternal and fetal risks, including fetal exposure to teratogenic medications and their safest and most effective contraception options.

Asking a patient about desire for pregnancy early and periodically (not only during perceived periods of change) and acknowledging her personal risk factors will ensure open dialog. New information supports a shift from the paradigm of discontinuing all RMD medications except prednisone, since pregnancy-compatible steroid-sparing disease-modifying antirheumatic drugs and biologic agents pose fewer short- and long-term risks to mother and infant. With adequate planning, treatment, and monitoring, most women with RMD can have successful pregnancies. Recent data indicate compatibility of many rheumatology medications both with lactation and with paternal use. The rheumatologist's familiarity with drug safety during these periods is important to maintain disease control and minimize mother and infant risk.

Fertility and postmenopausal issues are not uncommon in RMD patients. Recommendations regarding ART reflect a growing demand among patients with RMD for fertility therapies. Oocyte freezing is now widely available (197). Attention to disease activity and aPL status and discussion with reproductive endocrinology and infertility specialists will optimize safety. For patients undergoing CYC therapy, the greatest challenge is to consider preservation of gonadal function and to initiate protective treatment protocols. HRT is another issue of importance for postmenopausal RMD patients. Severe vasomotor symptoms may be debilitating and if affected patients do not have aPL, HRT may improve quality of life.

The strength of evidence on reproductive health topics in RMD patients is moderate at best, and usually low, very low, or nonexistent for many topics of interest. Identification of areas with weak evidence highlights research priorities. One need is to establish the long-term safety profile of highly effective contraceptives in RMD patients with and without aPL. Although low-dose aspirin for preeclampsia prophylaxis in SLE and aPL patients is a low-risk intervention, its effectiveness is not known. Management of OB APS is one area with moderately strong evidence, but treatment for women with recurring adverse

outcomes despite standard therapy is needed. Much in the field of prevention, screening, and management of NLE requires further study. There are very limited data on RMD medication effects on fertility and teratogenicity in men with RMD. Because women with RMD who plan to conceive, are pregnant, or are lactating are usually excluded from clinical trials, large-scale data about medication use in these populations are also lacking. Pregnancy registries collect these data but suffer reporting bias and may not reflect the racial and ethnic make-up of the patient population. Given the difficulties of collecting clinical data, research that focuses on better understanding of placental and breast physiology, as well as drug and antibody transport, may help inform decision-making.

With the development of this guideline, the ACR recognizes the key role of clinical rheumatologists not only in managing disease activity but also in understanding the interactions of RMDs and their therapies in the context of reproductive health. The most important goal of this guideline is to provide substance and direction for discussion between clinicians and patients. A second goal is to encourage development of close working relationships among rheumatologists, specialists in obstetrics-gynecology, maternal-fetal medicine, and reproductive endocrinology and infertility, and other involved clinicians. We present this guideline as a resource to share, discuss, and disseminate across specialties and patient groups.

ACKNOWLEDGMENTS

We thank Adegbenga Bankole, MD, Karen Costenbader, MD, MPH, and Michael Weisman, MD for serving on the Expert Panel. We thank Roger Levy, MD, PhD for participating in the initial guideline scoping meeting. We thank Liana Frankel, MD for leading the Patient Panel meeting, as well the patients who (along with authors Rachelle Crow-Hercher and C. Whitney White) participated in this meeting: Jenee Johnson, Kamanta Kettle, Nicole Lumpkin, Teona Osborne, Melissa Perry-Bell, Mera Ramkissoon, Zenethia Roberts, Kaci Jackson Sanderson, Paula Sosin, and Bene Williams. We thank the ACR staff, including Regina Parker for assistance in organizing the face-to-face Patient Panel and Voting Panel meetings and coordinating the administrative aspects of the project and Robin Lane for assistance in manuscript preparation. We thank Janet Waters for help in developing the literature search strategy and performing the literature search and updates, and Janet Joyce for peer-reviewing the literature search strategy.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Sammaritano had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception and design. Sammaritano, Bermas, Chakravarty, Chambers, Clowse, Lockshin, Marder, Kavanaugh, Simard, Somers, Steen, Yazdany, Turner, D'Anci.

Acquisition of data. Sammaritano, Bermas, Chakravarty, Chambers, Clowse, Lockshin, Marder, Laskin, Tedeschi, Barbhaiya, Bettendorf, Eudy, Jayatilleke, Shah, Sullivan, Tarter, Turgunbaev, D'Anci.

Analysis and interpretation of data. Sammaritano, Bermas, Chakravarty, Chambers, Clowse, Lockshin, Marder, Guyatt, Branch, Buyon, Christopher-Stine, Crow-Hercher, Cush, Druzin, Kavanaugh, Laskin, Plante, Salmon, Simard, Somers, Steen, Tedeschi, Vinet, White, Barbhaiya, Bettendorf, Eudy, Jayatilleke, Shah, Sullivan, Tarter, Birru Talabi, Turgunbaev, D'Anci.

This criteria set has been approved by the American College of Rheumatology (ACR) Board of Directors and the European League Against Rheumatism (EULAR) Executive Committee. This signifies that the criteria set has been quantitatively validated using patient data, and it has undergone validation based on an independent data set. All ACR/EULAR-approved criteria sets are expected to undergo intermittent updates.

The ACR is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

This article is published simultaneously in the December 2017 issue of *Annals of the Rheumatic Diseases*.

The views expressed herein are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs or the United States government, or the NHS, the National Institute for Health Research, or the Department of Health (UK).

Supported by the European League Against Rheumatism, the American College of Rheumatology, The Myositis Association, and in part by the NIH (Intramural Research Program and the National Institute of Environmental Health Sciences), the European Science Foundation for the Euromyositis Register, the Swedish Research Council (grant K2014-52X-14045-14-3), and the regional agreement on medical training and clinical research between the Stockholm County Council and the Karolinska Institutet. The project also received support (not financial support/funding) from different associations: the American Academy of Neurology, the Childhood Arthritis and Rheumatology Research Alliance (CARRA; CARRA Inc. is funded by the National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH), Friends of CARRA, the Arthritis Foundation, the European Neuromuscular Centre, the International Myositis Assessment and Clinical Studies Group, the Muscle Study Group, the Rheumatologic Dermatology Society, the Pediatric Rheumatology European Society network for juvenile dermatomysitis, and the Pediatric Rheumatology International Trials Organization. Drs. Chinoy and Cooper's work in myositis is supported in part by Arthritis Research UK (grant 18474) and the Medical Research Council (grant MR/N003322/1). Dr. Vencovsky's work in myositis is supported by the Ministry of Health, Czech Republic (Project for Conceptual Development of Research Organization grant 00023728).

Objective. **To develop and validate new classification criteria for adult and juvenile idiopathic inflammatory myopathies (IIM) and their major subgroups.**

Methods. **Candidate variables were assembled from published criteria and expert opinion using consensus methodology. Data were collected from 47 rheumatology, dermatology, neurology, and pediatric clinics worldwide. Several statistical methods were utilized to derive the classification criteria.**

Results. **Based on data from 976 IIM patients (74% adults; 26% children) and 624 non-IIM patients with mimicking conditions (82% adults; 18% children), new criteria were derived. Each item is assigned a weighted score. The total score corresponds to a probability of having IIM. Subclassification is performed using a classification tree. A probability cutoff of 55%, corresponding to a score of 5.5 (6.7 with muscle biopsy) "probable IIM," had best sensitivity/specificity (87%/82% without biopsies, 93%/88% with biopsies) and is recommended as a minimum to classify a patient as having IIM. A probability of ≥90%, corresponding to a score of ≥7.5 (≥8.7 with muscle biopsy), corresponds to "definite IIM." A probability of <50%, corresponding to a score of <5.3 (<6.5 with muscle biopsy), rules out IIM, leaving a probability of ≥50–<55% as "possible IIM."**

Conclusion. **The European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria for IIM have been endorsed by international rheumatology, dermatology, neurology, and pediatric groups. They employ easily accessible and operationally defined elements, and have been partially validated. They allow classification of "definite," "probable," and "possible" IIM, in addition to the major subgroups of IIM, including juvenile IIM. They generally perform better than existing criteria.**

Introduction

Idiopathic inflammatory myopathies (IIMs), collectively known as myositis, are heterogeneous disorders characterized by muscle weakness and muscle inflammation (1). The most common subgroups in adults are dermatomyositis (DM), polymyositis (PM), and inclusion body myositis (IBM) (2), and in children, juvenile DM (JDM).

The International Myositis Assessment and Clinical Studies group (IMACS) has developed consensus on outcome measures and definitions of improvement to be used in clinical trials for myositis (3,4). A prerequisite for clinical trials and other clinical studies is the inclusion of well-defined patient groups. A wide variety of diagnostic or classification criteria for myositis are used (2,5–16), but are generally derived empirically and not validated. The criteria of Bohan and Peter (7,8) are most widely used, but have limitations. Because they do not clearly specify how to exclude other forms of myopathy, they may misclassify IBM patients as having PM (13,17–19), and muscular dystrophies with inflammation as myositis, and each criterion is not defined explicitly. New discoveries in the last decade, such as myositis-specific autoantibodies, that are associated with distinct clinical phenotypes (2,20–22), may provide opportunities to

Submitted for publication March 14, 2017; accepted in revised form July 26, 2017.

improve the precision of classification, but have not been tested adequately (11,23).

The aim of this project was to develop classification criteria for adult and juvenile IIM. The specific goal was to define the minimum essential, easily available clinical and laboratory features to 1) distinguish IIM from mimicking conditions with high sensitivity and specificity, and 2) distinguish the major subgroups of IIM.

Methods

Study design. The International Myositis Classification Criteria Project (IMCCP), an international collaboration with experts from adult and pediatric rheumatology, neurology, dermatology, epidemiology, and biostatistics, was established in 2004 and followed at our best the European League Against Rheumatism (EULAR) and American College of Rheumatology (ACR) recommendations for development of classification criteria from that time or published soon thereafter (24,25). A steering committee and a larger working committee with experts in IIM were formed (see Supplementary Table 1 and Supplementary Appendix, available online on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract).

Using the nominal group technique, experts in IIM from the steering committee and the working committee (26–29) designed the study and validation experiments, assembled and defined candidate criteria from published myositis criteria (2,5–16) and other characteristics of myositis, and determined and assembled the IIM subgroup diagnoses and comparator conditions that were studied. A pilot study to assess the practicality of capturing the items showed a fair agreement of data availability from IIM and non-IIM cases (Supplementary Table 2, http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract). Input was obtained from myositis experts, by email to the IMACS network, and requesting comments on the items, to maximize face and content validity (24,25). The steering committee revised the list of variables based on the comments and further suggestions from the IMACS network, and 93 variables (Supplementary Table 3, http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract) were selected by the steering committee for study in cases and comparators. A glossary and definitions were developed according to an ACR glossary (30,31) (Supplementary Table 4, http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract). Data were abstracted from patients' records and entered into a web-based database.

Inclusion criteria for cases and comparators were 1) diagnosis for at least 6 months prior to study inclusion; 2) physician certainty of diagnosis—either known IIM or, as comparators, known non-IIM cases where myositis was considered in the initial differential diagnosis; and 3) patients with the most recent and complete data were prioritized to acquire the most complete data in a consistent manner. A maximum of 40 cases and an equal number of comparators were collected from each center.

The study was approved by the ethics committees at each site.

Data analysis and candidate criteria selection. The association of each variable with the diagnosis (IIM, non-IIM) was assessed by odds ratios and tested with the Fisher's exact test. The treating physician diagnosis was considered the gold standard for analysis. Three classification techniques were explored: 1) a sum-of-items model in which a patient was classified as a case if the patient had a specified number of items from a set of item; 2) a probability-score model; and 3) a classification tree. The ensuing candidate criteria were examined with respect to statistical performance and clinical relevance. Due to the observed superior discriminating performance of the probability-score model, the other models were set aside.

Criteria development. The probability-score model summed score points associated with the signs and symptoms present. The score points were obtained as coefficients of a logistic regression model used to combine multiple variables for predicting IIM. The statistical significance of the resulting increase in the goodness-of-fit of the model was assessed using the Wald test. The improvement in predictive ability was measured by the increment in specificity and sensitivity and summarized by the area under the receiver operating characteristic curve (AUC).

Pediatric experts are using fewer muscle biopsies for classification of JDM in clinical practice than adult rheumatologists. Thus, a second model not including biopsy variables was developed. Assessment of statistical performance for each score/probability cutoff value provided the basis for a recommendation of a cutoff value for IIM classification by the steering committee. The proposed cutoffs were then defined as possible, probable, and definite IIM. To facilitate use of the new criteria, a web-based calculator for the probability-score model was developed.

The new classification criteria were compared with previous IIM criteria. Their statistical performance, and number of patients per IIM subdiagnosis classified as IIM by the different criteria sets, were calculated.

To distinguish subgroups of patients classified with IIM according to the new criteria, a classification tree was developed. The tree was based on the variables in the new classification criteria, statistical analyses as described in a separate methodology paper, and on expert opinion.

Validation. The new criteria were internally cross-validated. Samples of equal size to the original sample were drawn from the entire population at random with replacement, so-called "bootstrap" samples (32). The bootstrap sample represented the training sample, and the remaining subjects not contained in the bootstrap sample constituted the validation sample. The probability score was applied to each bootstrap training sample separately and then utilized to predict IIM in the validation sample. The procedure was repeated in over 200 bootstrap samples, and the average AUC was calculated.

The performance of the new criteria for IIM including the subgroups was tested for sensitivity in 2 independent cohorts, the Euromyositis Register (https://euromyositis.eu/) and the Juvenile Dermatomyositis Cohort Biomarker Study and Repository (JDRG) (UK and Ireland) (https://www.juveniledermatomyositis.org.uk/).

The program Stata V.13 (StataCorp) was used for data management and statistical analyses. The statistical program R (R Core Team [2014]. R: a language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria. URL http://www.R-project.org/) was used for some analyses.

A report detailing the methodology will be submitted as a separate publication (manuscript submitted).

Results

Study population. Data from 976 IIM patients (74.5% adults; 25.5% children) (Table 1) were collected between 2008 and 2011 from 23 European, 17 North American, 1 South American, and 6 Asian sites, representing IIM subgroups of JDM (n = 248), PM (n = 245), DM (n = 239), IBM (n = 176), amyopathic DM (ADM) (n = 44), hypomyopathic DM (n = 12), immune-mediated necrotizing myopathy (IMNM) (n = 11), and juvenile PM (n = 1). A total of 624 comparators (81.6% adults; 18.4% children) (Table 1) representing a broad spectrum of conditions that can mimic IIM were included, comprising systemic inflammatory diseases (36.5%), muscle dystrophies (16.0%), drug-associated or toxin-associated myopathies (7.9%), motor neuron diseases/neuropathies (7.7%), metabolic myopathies (6.9%), myalgias (4.5%), dermatologic diseases (3.7%), endocrine myopathies (3.7%), infectious myopathies (4.5%), mitochondrial myopathies (2.4%), neuromuscular diseases (2.6%), other myopathies (1.9%), immune-mediated skin conditions (0.5%), as well as other diagnoses (1.3%) (see Supplementary Tables 5 and 6, available online on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract).

Candidate criteria selection and criteria development. Based on statistical models, 16 variables from 6 categories best distinguished IIM cases from comparators (Table 2), and each variable was assigned a weight (score) based on its influence to discriminate IIM from non-IIM. A total score was computed by adding score points corresponding to each criterion being present. The score can be converted into a probability of IIM (Figures A and B), by:

$$\text{Probability of IIM without muscle biopsy} = 1/[1 + \text{exponential}\ (5.33\ -\ \text{score})]$$

$$\text{Probability of IIM including muscle biopsy} = 1/[1 + \text{exponential}\ (6.49\ -\ \text{score})]^{*}$$

or by using the online web calculator (www.imm.ki.se/biostatistics/calculators/iim). Sensitivity and specificity for varying probability cutoffs are shown in Figures 1C and D.

Cutpoints for classification. The best balance between sensitivity and specificity was found for a probability of 55–60% for the criteria not including muscle biopsy data, and 55–75% when including muscle biopsies, or a total aggregated score of score of ≥5.5 and ≤5.7 (≥6.7 and ≤7.6 if biopsy is available).

Subacute (>2 weeks to ≤2 months)	237 (24.3)	88 (14.1)
Insidious (>2 months to years)	648 (66.4)	444 (71.2)
NA	46 (4.7)	28 (4.5)

* IIM = idiopathic inflammatory myopathies; IQR = interquartile range; NA = information not available.
† Onset of first symptoms assumed to be related to the disease.
‡ Time from first symptom to last clinical evaluation.
§ Time from diagnosis to last clinical evaluation.
¶ Onset and progression of the first symptoms of the syndrome to the full disease presentation.

* Correction added 16 August 2018 after online publication: the algorithms used for manual calculation of the score that a patient will obtain using the described classification criteria have been reversed.

Table 2. The European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria for adult and juvenile idiopathic inflammatory myopathies (IIMs)

When no better explanation for the symptoms and signs exists, these classification criteria can be used			
	Score points		
Variable	Without muscle biopsy	With muscle biopsy	Definition
Age of onset			
Age of onset of first symptom assumed to be related to the disease ≥18 years and <40 years	1.3	1.5	18 ≤ age (years) at onset of first symptom assumed to be related to the disease <40
Age of onset of first symptom assumed to be related to the disease ≥40 years	2.1	2.2	Age (years) at onset of first symptom assumed to be related to the disease ≥40
Muscle weakness			
Objective symmetric weakness, usually progressive, of the proximal upper extremities	0.7	0.7	Weakness of proximal upper extremities as defined by manual muscle testing or other objective strength testing, which is present on both sides and is usually progressive over time
Objective symmetric weakness, usually progressive, of the proximal lower extremities	0.8	0.5	Weakness of proximal lower extremities as defined by manual muscle testing or other objective strength testing, which is present on both sides and is usually progressive over time
Neck flexors are relatively weaker than neck extensors	1.9	1.6	Muscle grades for neck flexors are relatively lower than neck extensors as defined by manual muscle testing or other objective strength testing
In the legs, proximal muscles are relatively weaker than distal muscles	0.9	1.2	Muscle grades for proximal muscles in the legs are relatively lower than distal muscles in the legs as defined by manual muscle testing or other objective strength testing
Skin manifestations			
Heliotrope rash	3.1	3.2	Purple, lilac-colored, or erythematous patches over the eyelids or in a periorbital distribution, often associated with periorbital edema
Gottron's papules	2.1	2.7	Erythematous to violaceous papules over the extensor surfaces of joints, which are sometimes scaly. May occur over the finger joints, elbows, knees, malleoli, and toes
Gottron's sign	3.3	3.7	Erythematous to violaceous macules over the extensor surfaces of joints, which are not palpable
Other clinical manifestations			
Dysphagia or esophageal dysmotility	0.7	0.6	Difficulty in swallowing or objective evidence of abnormal motility of the esophagus
Laboratory measurements			
Anti–Jo-1 (anti–histidyl–transfer RNA synthetase) autoantibody present	3.9	3.8	Autoantibody testing in serum performed with standardized and validated test, showing positive result
Elevated serum levels of creatine kinase (CK)* *or* lactate dehydrogenase (LDH)* *or* aspartate aminotransferase (ASAT/AST/SGOT)* *or* alanine aminotransferase (ALAT/ALT/SGPT)*	1.3	1.4	The most abnormal test values during the disease course (highest absolute level of enzyme) above the relevant upper limit of normal
Muscle biopsy features—presence of:			
Endomysial infiltration of mononuclear cells surrounding, but not invading, myofibers		1.7	Muscle biopsy reveals endomysial mononuclear cells abutting the sarcolemma of otherwise healthy, non-necrotic muscle fibers, but there is no clear invasion of the muscle fibers
Perimysial and/or perivascular infiltration of mononuclear cells		1.2	Mononuclear cells are located in the perimysium and/or located around blood vessels (in either perimysial or endomysial vessels)
Perifascicular atrophy		1.9	Muscle biopsy reveals several rows of muscle fibers, which are smaller in the perifascicular region than fibers more centrally located
Rimmed vacuoles		3.1	Rimmed vacuoles are bluish by hematoxylin and eosin staining and reddish by modified Gomori trichrome stain

* Serum levels above the upper limit of normal.

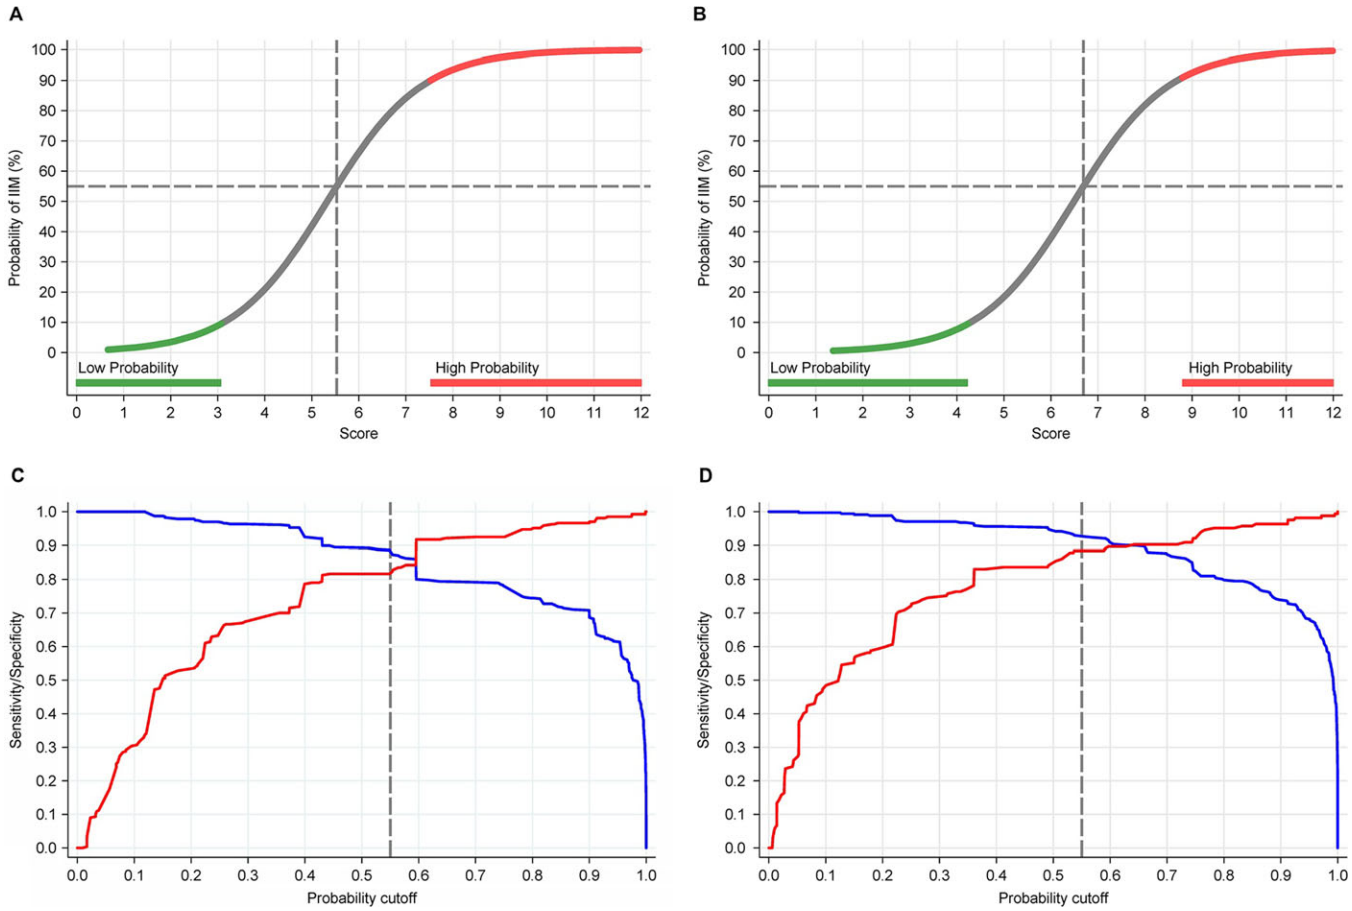

Figure 1. Probability of having idiopathic inflammatory myopathies (IIMs) based on the European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria for IIM. Each score obtained from the classification criteria corresponds to a probability of having the disease, without muscle biopsy data (**A**) or with muscle biopsy data (**B**). Each score and probability of disease display a unique set of sensitivity (blue line) and specificity (red line) measurements for the classification criteria not including muscle biopsy data (**C**) or including muscle biopsy data (**D**). The most optimal point of accuracy should be stated in publications and be appropriate to the intended purpose, with the recommendation of using a minimum of 55% probability (score of 5.5 without biopsies; 6.7 with biopsies) for classifying a case as IIM ("probable IIM") (dotted line). "Definite IIM" corresponds to a probability of at least 90% (score of ≥7.5 without biopsies; ≥8.7 with biopsies).

The IMCCP proposes that a patient may be classified as IIM if the probability exceeds a predetermined cutoff of at least 55% (corresponding to a score of ≥5.5, or ≥6.7 if biopsies are included) based on maximization of statistical performance and best balance between sensitivity and specificity. The level of probability ≥55% and <90% was defined as "probable IIM." The steering committee recommends, based on expert opinion, that "definite IIM" should equal a probability of ≥90%, corresponding to having total aggregate score of ≥7.5 without muscle biopsy and ≥8.7 with muscle biopsy.

Patients falling in the probability range ≥50% and <55% will be classified as "possible IIM." For a patient to be classified as a non-IIM patient, the probability would have to be <50% (score of <5.3 without biopsies; <6.5 with biopsies).

As suggested by pediatric experts and dermatologists, for patients with pathognomonic skin rashes of DM or JDM, classification criteria were developed, which did not include muscle biopsy data (Table 2). However, where no skin rash is present, a muscle biopsy is required for classification, as determined by a consensus of expert opinion within the IMCCP steering and working committees. Both sets apply equally well to adult IIM patients and to juvenile DM patients and should be used when IIM is suspected and no better explanation for the symptoms exists, as agreed on by expert opinion. Definitions for the criteria items are presented in Table 2.

Identification of subgroups. A patient classified with IIM by the EULAR/ACR classification criteria (probability of IIM ≥55%) can be further subclassified

Figure 2. Classification tree for subgroups of idiopathic inflammatory myopathies (IIMs). A patient must first meet the European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria for IIM (probability of IIM ≥55%). The patient can then be subclassified using the classification tree. The subgroup of polymyositis (PM) patients includes patients with immune-mediated necrotizing myopathy (IMNM). For inclusion body myositis (IBM) classification, one of the following is required for classification: finger flexor weakness and response to treatment: not improved (*), or muscle biopsy: rimmed vacuoles (**). *** = Juvenile myositis other than juvenile dermatomyositis (JDM) was developed based on expert opinion. IMNM and hypomyopathic dermatomyositis were too few to allow subclassification. ADM = amyopathic dermatomyositis; DM = dermatomyositis.

with a classification tree (Figure 2). Age at onset of first symptom (≥18 years of age) distinguishes adult from juvenile IIM. Thereafter, clinical findings and muscle biopsy features subclassify adult IIM patients into PM, IBM, ADM, or DM. Based on our data set, juvenile patients with skin rash can be classified into JDM. Three subgroups cannot be further separated using our criteria because of small sample sizes: juvenile PM, IMNM, and hypomyopathic DM.

Among patients with IIM by the EULAR/ACR classification criteria (probability of IIM ≥55%), and with sufficient data to allow subclassification (n = 703), the number of cases in the subgroups as defined according to the classification tree was enumerated (Table 3). The agreement between the classification tree subgroups and the physician-diagnosed subgroups in the data set was high (92.6% agreement; $\kappa = 0.90$, $P < 0.00001$). The agreement proportions, with a probability of 55%, were 1.00 for JDM, 0.89 for DM, 0.94 for ADM, 0.92 for IBM, and 0.93 for PM. Raising the probability cutoff of IIM to 90% yielded 94.9% agreement ($\kappa = 0.93$, $P < 0.00001$). With a probability cutoff of 90%, the agreement proportions were 1.00 for JDM, 0.96 for DM, 0.95 for ADM, 0.93 for IBM, and 0.88 for PM.

Performance of EULAR/ACR criteria compared with published criteria. Performance of the EULAR/ACR criteria was compared with published criteria for

Table 3. Comparison of physician-diagnosed idiopathic inflammatory myopathy (IIM) subgroups with IIM subgroups defined according to the classification tree among patients meeting the European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria for IIM*

	Classification tree subgroups†					
	JDM	DM	ADM	IBM	PM	Total
JDM	235	0	0	0	0	235

* JDM = juvenile dermatomyositis; DM = dermatomyositis; ADM = amyopathic dermatomyositis; IBM = inclusion body myositis; PM = polymyositis; IMNM = immune-mediated necrotizing myopathy.
† Classification of IIM by the EULAR/ACR classification criteria for IIM, using a 55% probability cutofff for classification, followed by the classification tree for subclassification.

IIM (7,8,10,11,14,15) using the IMCCP data set (Table 4). The new criteria including muscle biopsy features displayed high sensitivity (93%) and specificity (88%). There was slightly lower performance without biopsy variables (sensitivity and specificity 87% and 82%, respectively). Among the assessed criteria, the Targoff criteria (11) showed the highest sensitivity (93%) and specificity (89%). Other criteria had either high sensitivity and low specificity (Bohan and Peter [7,8] and Tanimoto criteria [10]), or low sensitivity and high specificity (Dalakas and Hohlfeld [14] and European Neuromuscular Centre [ENMC] criteria [15]).

We studied how different criteria could classify patients with diverse IIM subdiagnoses in the IMCCP data set (Table 4). The EULAR/ACR classification criteria correctly classified most patients with all IIM subdiagnoses. When biopsy data were used, the performance improved for IBM (94% with biopsy data versus 58% without biopsy data) and PM (86% with biopsy data versus 79% without biopsy data). The Bohan and Peter (7,8), Tanimoto (10), and Targoff (11) criteria correctly classified all IIM subdiagnoses except ADM, a diagnosis not included in those criteria. The Dalakas and Hohlfeld criteria (14) could not classify any subdiagnoses. The ENMC criteria (15) correctly classified DM and JDM cases but no other subdiagnoses.

A comparison between the EULAR/ACR classification criteria (55% probability cutoff) and the Bohan and Peter criteria (7,8) showed 89% agreement ($\kappa = 0.71$, $P < 0.00001$) without including muscle biopsy data, and 93% agreement ($\kappa = 0.73$, $P < 0.00001$) using muscle biopsy findings. Comparison between the newly developed criteria and the Targoff criteria (11) demonstrated that the agreement was 89% ($\kappa = 0.74$, $P < 0.00001$) and 93% ($\kappa = 0.82$, $P < 0.00001$) without or with inclusion of muscle biopsy data, respectively.

Validation. *Internal validation.* Using the criteria without muscle biopsy data, 733 observations were used,

§ Classification as idiopathic inflammatory myopathy per subgroup out of total number of cases per subgroup, expressed as the mean.

resulting in AUC = 0.942 and cross-validated area = 0.933. Using the criteria with muscle biopsy data, 507 observations were included, resulting in AUC = 0.962 and cross-validated area = 0.942.

External validation for sensitivity. Data from 592 cases (PM = 281, DM = 256, IBM = 33, JDM = 18, and ADM = 4) in the Euromyositis register were used where clinical, laboratory, and muscle biopsy data were available (Karolinska University Hospital, Stockholm, Sweden; Prague Hospital, Prague, Czech Republic; Oslo University Hospital, Oslo, Norway) (Supplementary Table 7, http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract). When there was sufficient information available, the EULAR/ACR classification criteria confirmed IIM diagnosis using a 55% probability cutoff for classification of IIM with no misclassification, yielding 100% sensitivity. Using the criteria without muscle biopsies, 489 patients (83%) were classified as IIM, and 103 patients (17%) could not be classified due to missing data. For the criteria with biopsies, 204 (34%) were classified as IIM and 388 (66%) could not be classified due to missing muscle biopsy data in the register. Results for the IBM and PM subgroups improved when biopsy data were included: 97% of IBM cases could be classified, compared with 73% when biopsy data were not included. For PM, 80% and 76%, respectively, could be classified. Raising the IIM classification cutoff from 55% to 90% decreased the total number of cases that could be classified to only 63% (not including muscle biopsies) or 28% (including muscle biopsies) due to absence of some muscle biopsy variables in the Euromyositis registry database.

The Juvenile Dermatomyositis Biomarker Study and Repository (UK and Ireland). The JDRG register included 332 juvenile IIM cases in the study (definite JDM = 292, probable JDM = 20, definite juvenile PM = 4, probable juvenile PM = 2, focal myositis = 6, and other IIM = 8) (Supplementary Table 8, http://onlinelibrary.wiley.com/doi/10.1002/art.40320/abstract). Muscle biopsy data were not available for all; thus the EULAR/ACR classification criteria without muscle biopsy data were used to test sensitivity in this data set. Three hundred seven cases (92%) could be classified using the 55% cutoff and no case was misclassified, yielding 100% sensitivity. The remaining 25 cases (8%) could not be classified due to missing data. Raising the cutoff stepwise to 60%, 70%, 80%, or 90% yielded classification of 92%, 88%, 87%, or 64% cases, respectively, where classification was possible.

Web-calculator. A web-calculator was developed (www.imm.ki.se/biostatistics/calculators/iim) as an aid to use the EULAR/ACR classification criteria. A probability range of classification can be obtained, providing the minimum and maximum probability. In addition to the probabilities acquired, the aggregated scores will be displayed. Whenever sufficient data are entered, the subclassification will be displayed.

Discussion

Classification criteria are essential for inclusion of comparable patients in studies. No validated classification criteria for IIM currently exist. The EULAR/ACR classification criteria for IIM offer advantages that previous criteria lack. They are data-driven, exhibit high sensitivity and specificity, and use a limited number of accessible, defined clinical and laboratory variables. Internal validation and testing in external cohorts confirmed excellent performance. Importantly, the new criteria capture the most frequent IIM subgroups and can be used for both adults and children for research studies and clinical trials.

The new EULAR/ACR classification criteria provide a score with a corresponding probability of having IIM. This provides investigators flexibility in inclusion criteria for different types of studies, for example, clinical trials requiring high specificity would warrant a high probability of IIM in the inclusion criteria, whereas epidemiologic studies requiring high sensitivity would need inclusion criteria with lower probability of IIM.

The new criteria are based on data from children and adults with different ethnicities from centers in Europe, America, and Asia, and use symptoms, signs, and other measures that are routinely assessed. A limitation is still that a majority of the patients were Caucasian, and even though we included data from 298 patients from Asia, we cannot exclude that there can be differences in manifestations between different ethnic groups; hence we still need to validate the criteria in Asian and African populations. Importantly, in patients with a typical DM skin rash, the criteria can be used without muscle biopsy data. For JDM, 97% of patients were correctly classified using the new criteria without muscle biopsy data. The new criteria also offer practical advantages in the number of variables needed to be tested. If a sufficient probability is reached, there is no requirement to test all items. Each criterion is well-defined, lessening the opportunities for ad hoc interpretation. The skin rash typical of DM contributed with high weights in the probability score. Skin biopsy is recommended in the absence of muscle symptoms (33,34). The EULAR/ACR classification criteria are the first myositis criteria to be validated and tested for sensitivity in other cohorts and revealed no misclassification.

Compared with most previous criteria, the new criteria are superior in sensitivity, specificity, and classifi-

cation accuracy. Classification criteria should have high sensitivity and specificity. The EULAR/ACR criteria demonstrated sensitivity and specificity of 87% and 82%, respectively, with even higher accuracy when muscle biopsies were included: 93% and 88%, respectively. Correctly classified patients were 86% and 91%, respectively, with and without inclusion of biopsies, and the criteria performed equally well for adult and juvenile cases. The Targoff criteria (11) also showed good statistical properties, but were not able to capture all subgroups of IIM as ADM patients were not included. Furthermore, the variables were not clearly defined in the Targoff criteria, and testing of more variables is required, including electromyography, which is not always easily accessible and may be painful for patients. Importantly, the EULAR/ACR criteria can be applied to myositis patients with overlap diagnoses, such as mixed connective tissue disease or systemic lupus erythematosus with myositis, since these patients were included among IIM cases.

There are limitations of the study; no controls or comparators were included in the external validation cohort, since the IMCCP study was designed before those recommendations from ACR/EULAR were in place, requiring future validation. A validation study using comparators is underway, but we encourage additional validation studies in different populations. Another limitation largely unavoidable in observational data is the high frequency of missing data in the derivation data set and validation samples, reflecting differences in practice patterns in evaluating patients. Nevertheless, 80% of cases and comparators had muscle biopsy data available, whereas magnetic resonance imaging (MRI) data and electromyography were only available for 38% and 29% of cases, respectively, reflecting their limited usage in clinical diagnosis. However, MRI data and electromyography examination are still important for diagnostic purposes of IIM. Patients studied had to have their disease for at least 6 months, which did not allow us to study new-onset patients. Importantly, these criteria are proposed as classification criteria in research and in clinical trials, not as diagnostic criteria (35).There is also some possibility that the cut points established for probable and definite myositis will need adjustment when tested with new populations of patients.

It took almost 10 years to assemble sufficient numbers of patients with these rare diseases, and 3 subgroups did not have enough subjects to study adequately. During this period, a new IIM subgroup became recognized, IMNM (36), of which only a few cases were included in the study. IMNM cases could thus not be distinguished from PM in the subclassification tree. Another subgroup with few cases was juvenile PM, making a data-derived distinction from JDM impossible. However, pediatric rheumatology experts in the IMCCP recommended that the adult subclassification of IIM could be used for juvenile PM by extrapolation (Figure 2). IBM cases were identified in the subclassification tree by the clinical features of finger flexor weakness and no response to treatment, or by the presence of rimmed vacuoles in muscle biopsies (37).

Another limitation was the low frequency of myositis-specific autoantibodies documented. Five myositis-specific autoantibodies were included: anti–Jo-1, anti–Mi-2, anti–signal recognition particle, anti–PL-7, and anti–PL-12 antibodies, and all were strongly associated with IIM. However, only anti–Jo-1 autoantibody had a significant number of observations (n = 1,062) to permit analyses and inclusion in the classification criteria. A future update of the EULAR/ACR classification criteria should include the more recently-identified myositis-specific autoantibodies (21,22), in addition to more patients with IMNM, ADM, hypomyopathic DM, and juvenile cases other than JDM.

Recommendations

- Patients with pathognomonic skin rashes (heliotrope rash, Gottron's papules, and/or Gottron's sign) of JDM or DM are accurately classified with the EULAR/ACR classification criteria without including muscle biopsy data. For patients without these skin manifestations, muscle biopsy is recommended. For DM patients without muscle involvement, a skin biopsy is recommended.
- The EULAR/ACR classification criteria provide a score and a corresponding probability of having IIM. Each probability displays a unique sensitivity and specificity. The best balance between sensitivity and specificity can be found for a probability of 55–60% (total aggregated score of ≥5.5 and ≤5.7) for the criteria not including muscle biopsy data, and 55–75% (total aggregated score ≥6.7 and ≤7.6) when including muscle biopsies. These cases are designated "probable IIM." The recommended cutoff needed for classifying a patient as having IIM is ≥55%.
- "Definite IIM" corresponds to a probability of ≥90% or a total aggregate score of 7.5 or more without muscle biopsy and 8.7 with muscle biopsy, and is recommended in studies where a high specificity is required.
- A patient is termed "possible IIM" if the probability is ≥50% and <55% (a minimum score of 5.3 without biopsies and 6.5 with biopsies).
- For clarity and transparency, both the descriptive term ("possible," "probable," or "definite") and the probability and the aggregated score should be reported in studies.

Conclusions

New classification criteria for IIM and the major IIM subgroups have been developed. These data-driven criteria have a good feasibility, high sensitivity and specificity, have been partly validated in external cohorts, and are superior to previous criteria in capturing different subgroups of IIM. Revision of the criteria in the future will be important when additional validated myositis autoantibody tests, imaging, and other tests are available in more IIM cases and comparator cases without IIM.

ACKNOWLEDGMENTS

We thank Elin Forslund for assistance with data registration. We thank Dr. Andrew Mammen and Dr. Mike Ward for critical reading of the manuscript. We are grateful for contribution of clinical data from investigators and for participants contributing with valuable input at IMCCP meetings.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Lundberg had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

American College of Rheumatology Provisional Criteria for Clinically Relevant Improvement in Children and Adolescents With Childhood-Onset Systemic Lupus Erythematosus

Hermine I. Brunner,[1] Michael J. Holland,[1] Michael W. Beresford,[2] Stacy P. Ardoin,[3] Simone Appenzeller,[4] Clovis A. Silva,[5] Francisco Flores,[1] Beatrice Goilav,[6] Pinar Ozge Avar Aydin,[1] Scott E. Wenderfer,[7] Deborah M. Levy,[8] Angelo Ravelli,[9] Raju Khubchandani,[10] Tadej Avcin,[11] Marisa S. Klein-Gitelman,[12] Nicolino Ruperto,[9] Brian M. Feldman,[8] and Jun Ying,[13] for the Paediatric Rheumatology International Trial Organisation and Pediatric Rheumatology Collaborative Study Group

Objective. To develop a Childhood Lupus Improvement Index (CHILI) as a tool to measure response to therapy in childhood-onset systemic lupus erythematosus (cSLE), with a focus on clinically relevant improvement (CRI_{cSLE}).

Methods. Pediatric nephrology and rheumatology subspecialists (n = 213) experienced in cSLE management were invited to define CRI_{cSLE} and rate a total of 433 unique patient profiles for the presence/absence of CRI_{cSLE}. Patient profiles included the following cSLE core response variables (CRVs): global assessment of patient well-being (patient-global), physician assessment of cSLE activity (MD-global), disease activity index score (here, we used the Systemic Lupus Erythematosus Disease Activity Index), urine protein-to-creatinine ratio, and Child Health Questionnaire physical summary score. Percentage and absolute changes in these cSLE-CRVs (baseline versus follow-up) were considered in order to develop candidate algorithms and validate their performance (sensitivity, specificity, area under the receiver operating characteristic curve [AUC]; range 0–1).

Results. During an international consensus conference, unanimous agreement on a definition of CRI_{cSLE} was achieved; cSLE experts (n = 13) concurred (100%) that the preferred CHILI algorithm considers absolute changes in the cSLE-CRVs. After transformation to a range of 0–100, a CHILI score of ≥54 had outstanding accuracy for identifying CRI_{cSLE} (AUC 0.93, sensitivity 81.1%, and specificity 84.2%). CHILI scores also reflect minor, moderate, and major improvement for values exceeding 15, 68, and 92, respectively (all AUC ≥0.92, sensitivity ≥93.1%, and specificity ≥73.4%).

Conclusion. The CHILI is a new, seemingly highly accurate index for measuring CRI in cSLE over time. This index is useful to categorize the degree of response to therapy in children and adolescents with cSLE.

INTRODUCTION

Systemic lupus erythematosus (SLE) is a complex, chronic, multisystem autoimmune inflammatory disease, with up to 20% of patients diagnosed during childhood (cSLE) (1,2). When lupus disease commences early in life rather than during adulthood, the prognosis is poorer, particularly due to multiorgan and kidney involvement (3,4). The course of cSLE is characterized by

Supported by the NIH (grants 5U01-AR-51868, P30-AR-AR47363, and 2UL1-RR-026314). Dr. Silva's work was supported by grants from Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP 215/03756-4), Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq 303422/2015-7 and CNPq 304255/2015-7), and by Núcleo de Apoio à Pesquisa "Saúde da Criança e do Adolescente" da USP (NAP-CriAd). Dr. Ardoin's work was supported by CNPq 7/2016-9.

SIGNIFICANCE & INNOVATIONS

- International consensus regarding a definition of clinically relevant improvement in children and adolescents with lupus has been achieved.
- The Pediatric Rheumatology International Trials Organization/American College of Rheumatology (ACR) provisional criteria for response to therapy in children with lupus have only fair accuracy for capturing clinically relevant improvement in children with lupus, as judged by physicians.
- Using strategies for the development of response measures in line with those suggested by the ACR, we newly developed and initially validated highly accurate criteria to measure clinically relevant improvement in children and adolescents with lupus.

episodes of disease flares followed by periods of improvement, generally due to more intensive drug therapy. There is international consensus that core response variables (cSLE-CRVs) should be considered when assessing response to therapy and cSLE disease flare (5,6). Considering changes in cSLE-CRVs, a provisional American College of Rheumatology (ACR) cSLE flare score can be calculated to identify patients who experienced a minor, moderate, or severe flare of cSLE (7,8). Likewise, percentage changes in cSLE-CRVs are the basis for the Pediatric Rheumatology International Trials Organization (PRINTO)/ACR provisional criteria for response to therapy (9).

We have previously shown, albeit in a rather small data set, that the PRINTO/ACR provisional criteria for response to therapy and, to a lesser extent, the Systemic Lupus Erythematosus Responder Index (SRI) are both very well suited to capture major improvement in cSLE; however, both the PRINTO/ACR provisional criteria for response to therapy and the SRI appeared less apt to identify patients who experienced moderate or minor improvement of cSLE (10). At present, there are no generally accepted criteria or algorithms to measure various degrees of improvement in cSLE, and consensus is lacking regarding what constitutes clinically relevant improvement (CRI_{cSLE}) in children and adolescents with cSLE. The latter is especially relevant, because in studies of rheumatoid arthritis, an ACR 20% improvement (ACR20) response, or in juvenile idiopathic arthritis (JIA) an ACR30 response (JIA-ACR30), provides such a measure of clinically relevant improvement. ACR20 and JIA-ACR30 responses, respectively, are regarded as improvement thresholds that can support labeling of new medications by the US Food and Drug Administration or the European Medicines Agency (11,12). Prior to developing criteria or algorithms to measure $CRI_{cSLE,}$ it is necessary to achieve consensus around a definition of CRI_{cSLE}.

Building on prior international consensus around the cSLE-CRVs that are needed to capture response to therapy in cSLE (9), the objectives of this study were to define CRI_{cSLE} and to develop, as well as initially validate, criteria to measure CRI_{cSLE}. Further, we sought to measure minor, moderate, and major responses to therapy in cSLE.

PATIENTS AND METHODS

The overall approach to this project was based on the methodologic framework successfully employed in pediatric rheumatology criteria development in the past (9,13,14), which is aligned with recommendations of the ACR Criteria Subcommittee and the Quality of Care Committee (15). As shown in Figure 1, an initial Delphi survey was conducted among 114 pediatric rheumatologists and nephrologists with expertise in cSLE (1) to delineate key features for judging whether a patient experienced CRI_{cSLE} (step 1). Subsequently, participants in a consensus conference rated 200 patient profiles (step 2). During a consensus conference, the results of steps 1 and 2 were reviewed to support consensus formation around a definition of CRI_{cSLE} (step 3)**.** This was followed by a second round of patient profiles sent to 200 pediatric rheumatologists and the cSLE experts who participated in the consensus conference. The resulting data set was randomly split into a training data set and a validation data set (step 4). The training data set was used to develop candidate criteria for CRI_{cSLE} (step 5). These candidate criteria were tested using the validation data set (step 6). As in step 3, agreement was achieved around a

Step 7:
Agreement of the preferred preliminary criteria of CRIcSLE

Figure 1. Process of developing the criteria for clinically relevant improvement of childhood-onset systemic lupus erythematosus (cSLE). Consensus formation methodology was used, starting with a Delphi survey, a series of online ratings of patient profiles (PPs) by physicians experienced in the care of children with cSLE, a consensus conference, and final consensus about preferred criteria to measure clinically relevant improvement of cSLE (CRI_{cSLE}).

preferred Childhood Lupus Improvement Index (CHILI) algorithm among cSLE experts with voting rights who had participated in the consensus conference (step 7). See Appendix A for a list of the members of the Pediatric Rheumatology Collaborative Study Group who contributed to steps 1 and 6.

Step 1: Delphi survey regarding CRI_{cSLE}. The 13 expert participants in the consensus conference and 100 of the pediatric rheumatologists who contributed to the development of other cSLE criteria sets (6,8) received a Delphi survey inquiring about cSLE (1) characteristics and changes in cSLE-CRVs that would support the presence of CRI_{cSLE}. The Delphi survey was piloted (HBR, PöA). Principles and recommendations for the design and conduct of online surveys were followed (16).

Step 2: patient profile ratings prior to the consensus conference. Using prospective data for cSLE patients in the Cincinnati Children's Hospital Medical Center Lupus Registry (17), the PRINTO Lupus Cohort (6), and a multicenter North American cSLE cohort (grant U01-AR-5868 to Dr. Brunner, Principal Investigator), we developed 1,482 unique patient profiles. After omitting patient profiles with >2 missing data elements and some patient profiles without changes in cSLE-CRVs between visits, there were 433 unique patient profiles. Missing observations in these 433 patient profiles were imputed using multiple imputation methods and expectation–maximization algorithms in computation (18–20).

Each patient profile provided the following patient data at the time of a baseline visit and a follow-up visit: 1) physician assessment of cSLE activity (MD-global) as measured on a visual analog scale (VAS) (0 = inactive disease and 10 = very active disease), 2) parent assessment of patient overall well-being (patient-global) as measured on a VAS (0 = very poor and 10 = very well), 3) proteinuria, measured by timed urine collection or protein-to-creatinine ratio in a spot urine specimen, 4) erythrocyte sedimentation rate (ESR), 5) levels of complement C3 and C4, 6) item and summary scores of the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) (21), and 7) the Child Health Questionnaire (version P50) physical summary score (CHQ-PhS) (5,6). Information about complete blood cell counts with differential, serum chemistry, ESR, urinalysis, and anti–double-stranded DNA antibody concentrations were also provided.

Thirteen cSLE experts (HIB, MWB, SPA, SA, CAS, FF, BG, SEW, DML, AR, RK, TA, and MKG) who were voting participants at a consensus conference were asked to rate 200 of the 433 patient profiles prior to the meeting. After the consensus conference, these cSLE experts plus 200 pediatric rheumatologists who previously participated in a similar patient profile rating exercise (6–8) were asked to rate 50 patient profiles each that were randomly selected from the pool of 433 patient profiles. Each patient profile rater was asked to assess the disease course (Question A), using the following response options: major improvement, moderate improvement, minor improvement, unchanged or worse, or "I do not have enough information to make this assessment." Further, if a patient profile rater considered improvement to be present, then he/she was asked whether or not improvement constituted CRI_{cSLE} (Question B). In this context, minor improvement can be considered equivalent to "any improvement" in cSLE. The survey source data were batch-processed, and open source online survey software, REDCap, was used for response management and as a presentation layer (see https://www.project-redcap.org/).

The minimum number of rater responses to each patient profile was 16, and all patient profiles were considered in the subsequent adjudication process. Considering that patient profile raters may not necessarily agree on the interpretation of the disease course for a given patient profile, the "true" overall course of cSLE for a

given patient profile was adjudicated using majority rule (i.e., the majority of the raters of a patient profile agreed on a given disease course). Other rules were calculated, including the 67% rule (i.e., at least two-thirds of the raters agreed on a given disease course. Irrespective of the rule used, results were similar to the majority rule. Hence, we present mainly the results from majority rule analyses.

Three statistical strategies were used to develop a series of candidate criteria to measure CRI_{cSLE}. We considered the PRINTO/ACR provisional criteria for response to therapy (9), which have been previously validated to measure improvement in cSLE (strategy 1). Furthermore, we developed algorithms that considered absolute change (strategy 2) or relative or percentage changes (strategy 3) in the cSLE-CRVs between baseline and follow-up, using multinomial logistic regression. Strategies 2 and 3 yield a numeric "CHILI score" (or log odds of improvement) calculated from the combined changes in the cSLE-CRV predictors between baseline and follow-up (9,22).

The accuracy of the PRINTO/ACR provisional criteria for response to therapy was tested using kappa statistics. With respect to the criterion standard (here, adjudicated disease course from the patient profile ratings), kappa values can be interpreted as follows: poor agreement, $\kappa < 0.4$; fair to good agreement, $\kappa = 0.4$–0.75; and substantial to excellent agreement, $\kappa > 0.75$. For each of the candidate CRI_{cSLE} algorithms from multinomial regression analysis, diagnostic accuracy was assessed by receiver operating characteristic (ROC) curve analysis. The area under the ROC curve (AUC; range 0–1) was calculated, and the diagnostic accuracy was considered outstanding, excellent, good, fair, or poor if the AUC was in the range of 0.9–1.0, 0.81–0.90, 0.71–0.80, 0.61–0.70, and <0.60, respectively (23).

Based on prior consensus (step 3), threshold CHILI scores reflect the highest conditional AUC among all candidate thresholds on the ROC curve, i.e., the point on the ROC curve with the highest precision of correctly classifying the degree of cSLE improvement level (CRI_{cSLE} minor, moderate, or major).

All analyses were conducted using SAS 9.4 and Systat 12 software. *P* values less than 0.05 were considered significant.

Step 3: consensus definition of CRI_{cSLE}. Participants in the consensus conference were experienced pediatric rheumatologists and nephrologists from South America, North America, Asia, and Europe who had substantial clinical and research experience in cSLE. PRINTO leadership (NR) participated in the discussions during the consensus conference as a non-voting content expert. A priori, the consensus level at the consensus conference was set at 75%, i.e., comparable or even somewhat higher than that chosen in previous similar studies (6,13,24). Using nominal group technique guided by an experienced moderator (BMF), the expert panel reached agreement around the definition of CRI_{cSLE}.

The panel also reviewed the performance of the provisional PRINTO/ACR criteria of response to therapy and candidate improvement algorithms derived by multinomial logistic regression using patient profile ratings from step 2, considering the Outcome Measures in Rheumatology filter (25–27): 1) feasibility, i.e., practicability: can the items be measured easily?; 2) reliability, i.e., reproducibility: can the items be measured precisely?; 3) redundancy: are there 2 or more items included in the candidate criteria measuring the same aspect of the disease?; 4) face validity, i.e., credibility: are the criteria sensible?; 5) content validity, i.e., comprehensiveness: do the criteria sample all of the domains of the disease?; 6) criterion validity: based on AUC, do the criteria accurately approximate the "gold standard," i.e., the adjudicated disease course as majority rule?; 7) sensitivity and specificity: do the criteria effectively identify patients with CRI_{cSLE} and/or various levels of improvement and distinguish them from patients who have not experienced CRI_{cSLE} and/or various levels of improvement?; and 8) discriminant validity: do the criteria detect the smallest clinically important change?: i.e., discriminate patients with one of the following disease courses: CRI_{cSLE}; minor improvement, moderate improvement, major improvement, unchanged or worse.

Step 4: second round of patient profile ratings. Besides individuals who were invited to participate in steps 1 and 2, the 433 patient profiles were then sent to another 100 pediatric rheumatologists who previously participated in a similar study (7). Therefore, a total of 213 patient profile raters received 50 randomly selected patient profiles each; formats, response options, and adjudication were described in step 2. The resulting data set was divided, in the sequence of acquisition, into a training data set and a validation data set.

Steps 5 and 6: development and preliminary validation of the CHILI. Using the training data set (step 4), we newly developed candidate algorithms to measure improvement (CRI_{cSLE}; minor, moderate, or major) as described in step 2. In these algorithms, CRI_{cSLE} was considered to be a special threshold score among many possible improvement scores. Threshold scores were transformed to range between 0 and 100. The algorithms and thresholds developed in the training data set (step 5) were validated using the validation data set to derive preliminary CHILI criteria (step 6).

Step 7: ranking of preliminary CHILI algorithms after the consensus conference. The analyses from steps 5 and 6 were presented to the consensus conference participants who had voting rights. These cSLE experts were asked whether, in the setting of a clinical trial, 1) use of CRI_{cSLE} algorithms from multinomial logistic regression was preferable to the use of the PRINTO/ACR provisional criteria for response to therapy 2) absolute differences in the cSLE-CRVs were superior to percentage changes when measuring CRI_{cSLE}, and 3) these algorithms were useful for categorizing the degree of improvement (minor, moderate, or major) in cSLE.

RESULTS

Definition of CRI_{cSLE}. The survey (step 1) inquired about changes in cSLE-CRVs, signs, and symptoms that would support the presence of CRI_{cSLE}. Among the 113 pediatric rheumatologists and nephrologists approached for survey participation, 92 (81%) responded. Survey participants from different regions or less versus more than 10 years of experience in treating cSLE did not differ significantly in their responses (data not shown). There was ≥80% agreement that, with CRI_{cSLE}, the MD-global and/or the score for a disease activity index must be better or unchanged and that patients with CRI_{cSLE} could experience new organ involvement as long as it did not involve the neuropsychiatric, hematologic, gastrointestinal, renal, ophthalmologic, or cardiopulmonary organ system. The initial ratings of 200 patient profiles provided additional data regarding the measurement of CRI_{cSLE} (see Supplementary Table 1 [available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23834/abstract] for adjudication results). After review of this information during the consensus conference (step 3), there was 100% agreement for the following consensus definition of CRI_{cSLE}: "A clinically relevant improvement has occurred in a child with lupus if there are reduced signs of disease from active lupus. Although there may not be improvement of lupus activity in all organ systems, there cannot be increased lupus activity in a major organ system, i.e., neuropsychiatric hematological, gastrointestinal, renal, ophthalmological, or cardiopulmonary organ system. Patient symptoms will be at least stable, and immunosuppressive therapy should be unchanged or decreased." Further, cSLE experts concluded that further testing of the PRINTO/ACR provisional criteria for response to therapy in cSLE was warranted, and that multinomial logistic regression modeling should be pursued to measure CRI_{cSLE} with threshold choice at the statistical optimal point on the AUC (≥92% agreement for both).

Post–consensus conference patient profile ratings. As part of step 4, the 433 patient profiles were sent to 213 patient profile raters. The response rate was 91% (194 of 213), and all 433 patient profiles qualified for adjudication. The resulting data set was split into a training data set (200 patient profiles) and a validation data set (n = 233). Baseline characteristics of the patients represented in these data sets are shown in Table 1. When the majority rule was applied, there were 95 (47.5%) patient profiles without CRI_{cSLE} and 105 patient profiles (52.5%) with CRI_{cSLE} in the training data set. Among patient profiles adjudicated to reflect CRI_{cSLE}, 83% were considered to represent moderate or major improvement of cSLE, while 99% of patient profiles without CRI_{cSLE} were adjudicated to reflect, at most, minor improvement in cSLE.

Performance of individual cSLE-CRVs to measure CRI_{cSLE}. Based on univariate logistic regression in the training data set, absolute changes and percentage (or relative) changes in the cSLE-CRVs had similar discriminative properties to detect CRI_{cSLE} (Table 2). However, only absolute changes in the urine protein-to-creatinine ratio ($P < 0.001$) between baseline and follow-up but not percentage changes

Table 2. Discriminative properties of absolute and relative (percentage) changes in the cSLE core response variable for capturing CRI_{cSLE} in the training data set*

* Values for sensitivity and specificity are the percent. cSLE = childhood-onset systemic lupus erythematosus; CRI_{cSLE} = clinically relevant improvement in cSLE (see Table 1 for other definitions).
† Sensitivity and specificity calculated at the threshold score.
‡ Optimal score from univariate logistic regression to discriminate between the presence versus absence of CRI_{cSLE}.
§ Values are the mean ± SD from absolute differences between the baseline and follow-up time points.
¶ Values are the percentage change at the time of the follow-up visit relative to the baseline visit.

(P = 0.132) significantly differed between patients with and those without CRI_{cSLE}. Compared with the other cSLE-CRVs but irrespective of the type of change (absolute, relative) considered, the urine protein-to-creatinine ratio had only fair accuracy (AUC ≤ 0.67) for capturing CRI_{CSLE}. Individually, the MD-global and the SLEDAI had the highest accuracy (AUC ≥ 0.90 for both) for identifying CRI_{CSLE} status.

Performance of the PRINTO/ACR provisional criteria for response to therapy to measure CRI_{cSLE}. As shown in Table 3 and Supplementary Table 2 (available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23834/abstract), in both the training data set and validation data set, the PRINTO/ACR provisional criteria for response to therapy had, at most, fair accuracy for capturing CRI_{cSLE} status ($\kappa \leq 0.3$ for the majority rule and $\kappa \leq 0.43$ for the 67% rule). The same was also true for measuring various levels of improvement ($\kappa < 0.34$ for both the majority rule and the 67% rule).

Development of the CHILI to measure CRI_{cSLE}. As part of the step 5 analyses (Table 4), we used multinomial regression to generate candidate algorithms using the cSLE-CRVs that have

* The table was adapted from reference 9 (Ruperto et al, 2006). Values for sensitivity and specificity are the percent. PRINTO = Pediatric Rheumatology International Trials Organization; ACR = American College of Rheumatology; EULAR = European League Against Rheumatism; cSLE = childhood-onset systemic lupus erythematosus; CRI_{cSLE} = clinically relevant improvement in cSLE (see Table 1 for other definitions).
† The 4 highest-ranking algorithms (DI11, DI08, DI17, DI12) are shown. Ratio (n/m) designates the number of the 5 cSLE core response variables CRVs (MD-global, patient-global, Disease Activity Score, urine protein-to-creatinine ratio from spot urine or estimated by 24-hour timed urine collection) with improvement.
‡ The kappa value provides agreement between the provisional PRINTO/ACR/EULAR criteria for response to therapy and patient profile ratings from step 2, adjudicated using the majority rule.

been considered relevant for capturing improvement of cSLE (6,22). Irrespective of the type of change, i.e., absolute or percentage differences in the cSLE-CRVs between baseline and follow-up, algorithms had similar accuracy (AUC) for measuring CRI_{cSLE}. For example, using the algorithm that considered absolute changes in the cSLE-CRVs, a logit score of 0.16 or, after transformation to a scale of 0 to 100, a CHILI score of 54 was 89.5% sensitive and 92.6% specific for capturing CRI_{cSLE} status correctly (AUC 0.97) in the development data set. When considering percentage changes in the cSLE-CRVs between visits in the algorithm instead, a CHILI score of 60 had similar measurement properties (AUC 0.96, sensitivity 87.6%, specificity 92.6) for capturing CRI_{cSLE} status (Figure 2).

Initial validation of the CHILI algorithms. Algorithms considering absolute changes rather than percentage changes in the cSLE-CRVs were similarly robust, i.e., they maintained their accuracy (AUC) similarly well as the validation data set. Using the model parameters and threshold scores obtained from the training data set, the AUC of discrimination between patients who had CRI_{cSLE} as compared to those who did not was 0.93 (Figure 2). Hence, a CHILI score of 54 (absolute changes in the cSLE-CRVs are considered) represents the optimal threshold score based on the training data set. This CHILI score of 54 is 81.1% sensitive and 84.2% specific for CRI_{cSLE} in the validation data set.

Use of the CHILI to identify minor, moderate, and major response to cSLE therapy. As shown in Figure 2 and Table 4, the CHILI algorithms developed and validated to measure CRI_{cSLE} were also excellent for discriminating patients with various levels of improvement (minor, moderate, or major) between baseline and follow-up. Again, algorithms considering absolute differences and percentage differences in the cSLE-CRVs between baseline and follow-up performed similarly well in both the training data set and the validation data set.

Ranking of the candidate CHILI algorithms. The results for performance of the PRINTO/ACR provisional criteria for response to therapy, CHILI algorithms considering percentage change, and

	Percentage	0.95	91.7%	84.9%	**2.46**	**92**	0.94	98.4%	77.7%
CHILI‡ using absolute changes (Δ) of cSLE-CRVs	Improvement Logit Score (y)= - (5.1 + 0.47 x ΔSLEDAI + 0.7 x ΔMD-global + 1.1x Δ UPCR + 0.32 x ΔPatient-global - 0.002x ΔCHQ-PhS) Improvement Score (0-100) = 100• {EXP(y) / [1+EXP(y)]}								
CHILI‡ using percentage changes ($\Delta_{\%}$) of cSLE-CRVs	Improvement Logit Score (y) = - (6.1 + 6.5x $\Delta_{\%}$SLEDAI + 6.1X $\Delta_{\%}$MD-global + 0.02x $\Delta_{\%}$UPCR + 0.48x $\Delta_{\%}$Patient-global - 0.43x $\Delta_{\%}$CHQ-PhS) Improvement Score (0-100) = 100• {EXP(y) / [1+EXP(y)]}								

* Predictors used in a multivariate logistic model can be either from absolute differences between the baseline and follow-up time points OR percentage changes at the time of follow-up relative to the baseline visit in the development data set. An improvement logit score can be converted into an improvement score (range 0–100) using the formula: Improvement Score = 100*EXP(Improvement logit score)/[1+ EXP(Improvement logit score)]. Either a higher (or lower) improvement logit score or improvement score indicates higher (lower) likelihood of improvement. For a classification purpose, a patient's improvement score can be compared against the threshold score.
† Majority rule; Δ change score between baseline and follow-up visits.
‡ Improvement logit scores were calculated using multivariate logistic models. UPCR: urine protein to creatinine ratio from random urine sample; SLEDAI: SLE disease activity summary score; MD-global: physician global assessment of cSLE activity; Patient-global: patient assessment of overall well-being; CHQ-PHS Child Health Questionnaire, P50 version Physical function summary score.

CHILI algorithms considering absolute changes in the cSLE-CRVs were presented to the consensus conference participants who had voting rights. There was consensus (100%) that the CHILI algorithms were preferable to the PRINTO/ACR provisional criteria for response to therapy to measure CRI_{cSLE} as well as various levels of improvement in clinical trials of cSLE. Furthermore, CHILI algorithms using absolute changes were favored over those using percentage changes in the cSLE-CRVs, given their ease of use. Although scaling to a range of 0 to 100 was favored, there were some concerns that transformation might be mathematically challenging.

DISCUSSION

This international study investigated clinically important improvement in children with cSLE. In addition to a consensus definition of CRI_{cSLE}, we developed and initially validated the CHILI to serve as provisional criteria to measure CRI_{cSLE}. A composite measure to capture CRI_{cSLE} is necessary, because there is no single sign, clinical test, or patient symptom that is adequately sensitive and simultaneously specific for the presence of CRI_{cSLE}. Furthermore, we confirm that the CHILI is able to accurately describe the degree of cSLE improvement.

Several pediatric rheumatology response measures, such as the JIA-ACR30 criteria to capture response to therapy with JIA, consider relative (or percentage) changes in core response variables. While CHILI algorithms using percentage and absolute changes performed similarly in terms of accuracy, sensitivity, and specificity at the proposed threshold scores, we consider CHILI scores calculated from absolute changes in the cSLE-CRVs to be easier to compute, hence preferable. This is consistent with

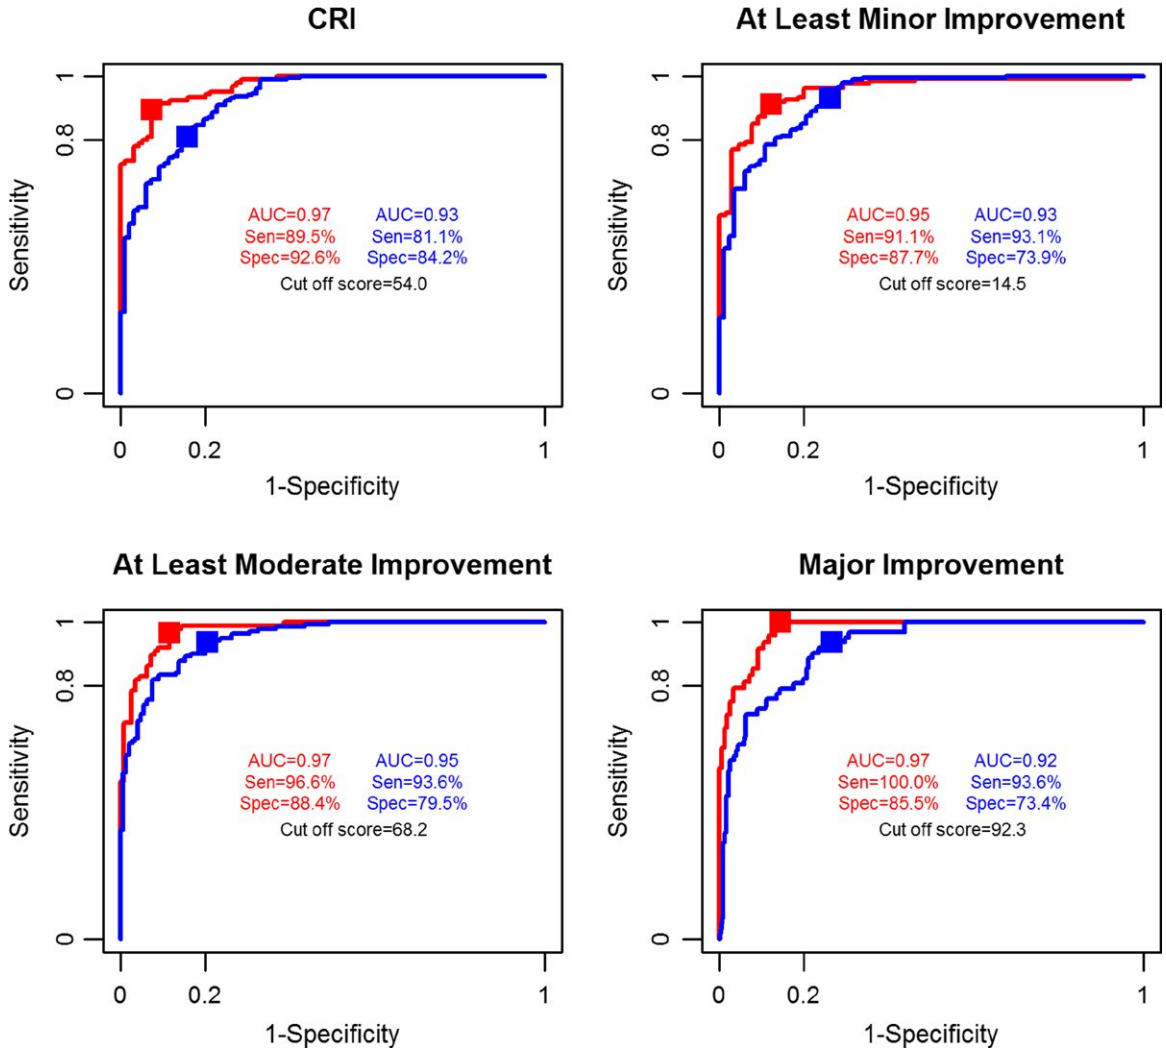

Figure 2. Performance of Childhood Lupus Improvement Index (CHILI) when considering absolute of the cSLE core response variables between baseline and follow-up in the development data set and the validation data set. The accuracy of the CHILI algorithm is largely maintained in the validation data set (blue) as compared to the training data set (red). As shown in panel labeled CRI a CHILI score of 54 (range 0–100) was 81.1% sensitive (Sen) and 84.5% specific (Spec) in the validation data set to capture CRI_{cSLE}, with an overall accuracy (area under the receiver operating characteristic curve [AUC]) of 0.93. CHILI algorithms developed and validated to measure CRICSLE were also excellent in discriminating patients with various levels of improvement (minor, moderate, major) between baseline and follow-up. CRI = clinically relevant improvement (see Figure 1 for other definitions).

the recently published ACR provisional criteria for global flares in cSLE (7,28). Indeed, more complex mathematical maneuvers beyond addition and multiplication are avoided, which is different from the Disease Activity Score in 28 joints, which includes a square root calculation, for example (29). For reasons associated with scaling, we transformed the CHILI scores to range from 0 to 100, with higher scores reflecting a larger degree of improvement. Whether such mathematical transformation maneuvers improve the ease of use of the CHILI will need to be studied in the future.

Different from the ACR provisional criteria for global flares in cSLE (7), the CHILI considers patient perspectives more comprehensively. Specifically, changes in patient overall well-being and physical function (CHQ-PhS) are included in the algorithm. This is consistent with the results of earlier discussions of how to capture response to therapy in cSLE (6,8).

Currently, the SRI is the principal outcome measure used in clinical trials in adults with SLE. We have shown that the PRINTO/ACR provisional criteria for response to therapy in cSLE (9) are more accurate than the SRI in capturing improvement in cSLE (10). In the current study, we confirmed that the PRINTO/ACR provisional criteria for response to therapy seem to have, at best, fair accuracy for capturing the true course of cSLE, including CRI_{cSLE}. Different from the CHILI, in the PRINTO/ACR provisional criteria for response to therapy all cSLE-CRV changes are considered equally (same percentage changes) relevant for measuring response to therapy. However, from a measurement point of view, as supported by the consensus definition for CRI_{cSLE} and our univariate analysis, the cSLE-CRVs have differential importance to clinicians when judging the disease course in a child with cSLE (10). Taken together, the PRINTO/ACR provisional criteria for response to therapy—and by extension the SRI—can be used in clinical trials of cSLE but likely require sample sizes larger than those using the CHILI to capture response to therapy.

A limitation of our study might be that we were unable to test whether consideration of the British Isles Lupus Activity Group index (30) or other disease activity indices instead of the SLEDAI as a measure of cSLE activity would have allowed us to accurately identify cSLE patients who experienced CRI_{cSLE}. Indeed, the cSLE-CRVs do not specify which validated measures of cSLE activity are considered for the assessment of patients' response to therapy (9). We used the SLEDAI, given its ease of use and widespread acceptance around the world. Additional research will be required to assess whether other disease activity index scores can be used interchangeably. In addition, we did not provide patient profile raters with consensus definitions of what constitutes minor, moderate, and major improvement. Nonetheless, the accuracy of the CHILI algorithm performed well in the data sets used in this study. Last, we focused on the majority rule to adjudicate the disease course presented in the various patient profiles, which might have introduced bias. However, use of the 67% rule yielded results comparable to those using the CHILI.

The ACR has outlined a series of validation steps necessary before new criteria are to be widely used for clinical care or research (15,31). One step is to use data from clinical trials to develop response criteria. However, such data from interventions that impact cSLE activity currently are unavailable. Thus, we used the patient profile raters' perceptions of the course of cSLE instead. Given the prospective character of our data and the expertise of the patient profile raters, we considered the quality of the training data set and the validation data set to be high, and the number of patient profiles to assess CRI_{cSLE} yielded a robust CHILI.

In summary, a methodologically stringent process was used to develop a novel index to measure global improvement or response to therapy in cSLE. This provisional CHILI instrument can be used to help identify children with cSLE who have experienced a clinically relevant improvement and to categorize the degree of improvement as minor, moderate, or major. However, additional testing in independent data sets is required to confirm the performance characteristics of the CHILI when used in cSLE.

ACKNOWLEDGEMENTS

We thank Kasha Wiley (overall study coordination), Susan Priest (consensus conference logistics), Carly Muller, Malea Rolfsen, Allen Watts, Gaurav Gulati, and Jamie Meyers-Eaton (patient profile testing) from Cincinnati Children Hospital Medical Center (CCHMC) as well as CCHMC Biomedical Informatics (web-based data management application development). American College of Rheumatology Provisional Criteria for Global Flares in Childhood-Onset Systemic Lupus Erythematosus

HERMINE I. BRUNNER,[1] MICHAEL HOLLAND,[1] MICHAEL W. BERESFORD,[2] STACY P. ARDOIN,[3] SIMONE APPENZELLER,[4] CLOVIS A. SILVA,[5] FRANCISCO FLORES,[1] BEATRICE GOILAV,[6] SCOTT E. WENDERFER,[7] DEBORAH M. LEVY,[8] ANGELO RAVELLI,[9] RAJU KHUNCHANDANI,[10] TADEJ AVCIN,[11] MARISA S. KLEIN-GITELMAN,[12] BRIAN M. FELDMAN,[8] NICOLINO RUPERTO,[9] JUN YING,[13] FOR THE PRCSG AND PRINTO INVESTIGATORS*

Objective. **To validate the preliminary criteria of global flare for childhood-onset SLE (cSLE).**

Methods. **Pediatricians experienced in cSLE care (n = 268) rated unique patient profiles; results of standard cSLE laboratory testing and information about the cSLE flare descriptors were presented as follows: global assessment of patient well-being, physician global assessment of disease activity (MD-global), Disease Activity Index score, protein/creatinine ratio (PCR), and erythrocyte sedimentation rate (ESR). Using rater interpretation of the course of cSLE (baseline versus followup as the gold standard), performance (sensitivity, specificity, area under the receiver operating characteristic curve [AUC]) of the preliminary flare criteria was tested. An international consensus conference was held to rank the preliminary flare criteria as per the American College of Rheumatology recommendations and delineate threshold scores for minor, moderate, and major flares.**

Results. **The accuracy of the 2 highest-ranked candidate criteria that consider absolute changes (Δ) of the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) or British Isles Lupus Assessment Group (BILAG) (numeric scoring: A = 12, B = 8, C = 1, and D/E = 0), MD-global, PCR, and ESR were confirmed (both AUC >0.93). For the SLEDAI-based criteria (0.5 × ΔSLEDAI + 0.45 × ΔPCR + 0.5 × ΔMD-global + 0.02 × ΔESR) flare scores ≥6.4/3.0/0.6 constituted major/moderate/minor flares, respectively. For the BILAG-based algorithm (0.4 × ΔBILAG + 0.65 × ΔPCR + 0.5 × ΔMD-global + 0.02 × ΔESR) flare scores ≥7.4/3.7/2.2 delineated major/moderator/minor flares, respectively. These threshold values (SLEDAI, BILAG) were all >82% sensitive and specific for capturing flare severity.**

Conclusion. **Provisional criteria for global flares in cSLE are available to identify patients who experienced a flare. These criteria also allow for discrimination of the severity of cSLE exacerbations.**

INTRODUCTION

Systemic lupus erythematosus (SLE) is a complex, chronic, multisystem autoimmune inflammatory disease, with up to 20% of patients diagnosed during childhood (cSLE) (1,2). When disease commences early in life rather than during adulthood, it has a less favorable prognosis, particularly due to multiorgan and kidney involvement (3,4). The course of cSLE is characterized by episodes of disease flares, followed by periods of improvement, generally due to more intensive drug therapy. There is international consensus that a flare of cSLE is "a measurable worsening of disease activity in at least one organ system, involving new or worse signs of disease that may be accompanied by new or worse SLE

Supported by the NIH (grants 5U01-AR-51868, P30-AR-AR47363, and 2UL-1RR-026314) and by LUPUS UK, who supports the UK Juvenile-Onset Systemic Lupus Erythematosus Cohort Study, along with the NIHR Clinical Research Network (CRN), NIHR CRN Children's Specialty Group, and NIHR Alder Hey Clinical Research Facility. Significance & Innovations

- Results of the preliminary validation of criteria of global flare for childhood-onset systemic lupus erythematosus are provided.
- Based on the flare scores, mild, moderate, and severe flares can be defined.

symptoms; depending on the severity of the flare, more intensive therapy may be required" (5). Further, using consensus formation techniques, agreement has been achieved regarding preliminary criteria of global flares of cSLE based on changes of the erythrocyte sedimentation rate (ESR), the protein/creatinine ratio (PCR), physician global assessment of cSLE activity (MD-global), and the score of the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) (6,7) or the British Isles Lupus Activity Group index (BILAG) (8). Moreover, there is consensus around the need to discriminate flares as per their severity: mild/minor, moderate, and major/severe flares (5). However, there are no generally accepted criteria or algorithms to determine how to measure the severity of cSLE flares, nor have the preliminary cSLE flare criteria been validated in an independent data set. Thus, the objectives of this phase of the project were to validate the preliminary criteria of global flare of cSLE and to apply consensus formation methodology to define flare threshold levels for minor, moderate, and major flares. These criteria were created to define cSLE flares and their severity for use in clinical trials.

PATIENTS AND METHODS

The overall approach to this project was based on the methodologic framework successfully employed in pediatric rheumatology criteria measures in the past (9–11), aligned with recommendations of the American College of Rheumatology (ACR) Criteria Subcommittee and the Quality of Care Committee (12). The initial results of the consensus process resulting in preliminary cSLE flare criteria have been described elsewhere (5,13). Briefly, previous research demonstrated that the scores of a disease activity measure alone are inadequate for identifying flares (5). International agreement was reached regarding preliminary criteria to measure global flares of cSLE. Pediatric rheumatologists participated in Delphi surveys that yielded consensus around a common definition of cSLE global flares, and the delineation of cSLE flare descriptors. This was followed by exploration of candidate flare criteria (5) and the identification of preferred algorithms of global cSLE flares (14). Notably, data and analyses all suggested that uniform percentage changes of the cSLE flare descriptors are insufficient to capture cSLE flares with high sensitivity. Further, inclusion of the MD-global assessment of cSLE activity in highly accurate cSLE candidate flare algorithms proved necessary (5,15). During the first consensus conference, the top-performing candidate flare algorithms, derived either from multinomial logistic regression modeling or classification tree analysis (CART), were established.

We now present the phase of the project aimed at validating the preferred preliminary flare algorithms (14) via testing in an independent validation data set (Figure 1). These encompassed patient profile (PP) ratings that were requested from 503 pediatric rheumatologists from Australia, Africa, Asia, Europe, and the Americas who were members of at least 1 of the following organizations: the Pediatric Rheumatology Collaborative Study Group, the Childhood Arthritis Rheumatology Research Alliance, the Pediatric Rheumatology European Society Juvenile Lupus Working Group, and the Pan American League of Associations for Rheumatology (step 1).

The interpretation of the flare or "true" disease course of a given PP was determined using 2 approaches, which resulted in 2 distinct data sets for the subsequent validation exercises (step 2). Using the PP ratings, the preliminary criteria for cSLE global flares were tested for their ability to discriminate patients who experienced different levels of flares (minor, moderate, and major) (step 3). Subsequently, during a consensus conference, the validity of the criteria was critically reviewed, taking into consideration information from the medical literature, statistical performance, reliability, feasibility, and face validity as per the ACR guidance document (12) and the Outcome Measures in Rheumatology filter (16) (step 4).

Preliminary cSLE flare algorithms. We considered the top 4 preliminary flare algorithms (identified in the first consensus conference) based on feasibility, truthfulness, and discrimination (17). Two of the 4 preliminary cSLE flare algorithms (SLEDAI-based criteria: $0.5 \times \Delta\text{SLEDAI} + 0.45 \times \Delta\text{PCR} + 0.5 \times \Delta\text{MD-global} + 0.02 \times \Delta\text{ESR}$, and BILAG-based criteria: $0.4 \times \Delta\text{BILAG} + 0.65 \times \Delta\text{PCR} + 0.5 \times \Delta\text{MD-global} + 0.02 \times \Delta\text{ESR}$) were derived by multinomial logistic regression that considered several of the cSLE flare descriptors, and that yield "flare scores" (or log odds of flare), with a higher score representing a higher likelihood of a flare to have occurred. The other 2 algorithms of the top preliminary flare criteria were derived from CART (SLEDAI-CART: where score = 4 if $3 \leq$ SLEDAI, score = 3 if $0.7 \leq$ PCR and $3 >$ SLEDAI, score = 2 if $2 \leq$ MD-global and $0.7 >$ PCR and $3 >$ SLEDAI, and score = 1 if otherwise, and BILAG-CART: where score = 4 if $2 \leq$ BILAG, score = 3 if $0.7 \leq$ PCR and $2 >$ BILAG, score = 2 if $2 \leq$ MD and $0.7 >$ PCR and $2 >$ BILAG,

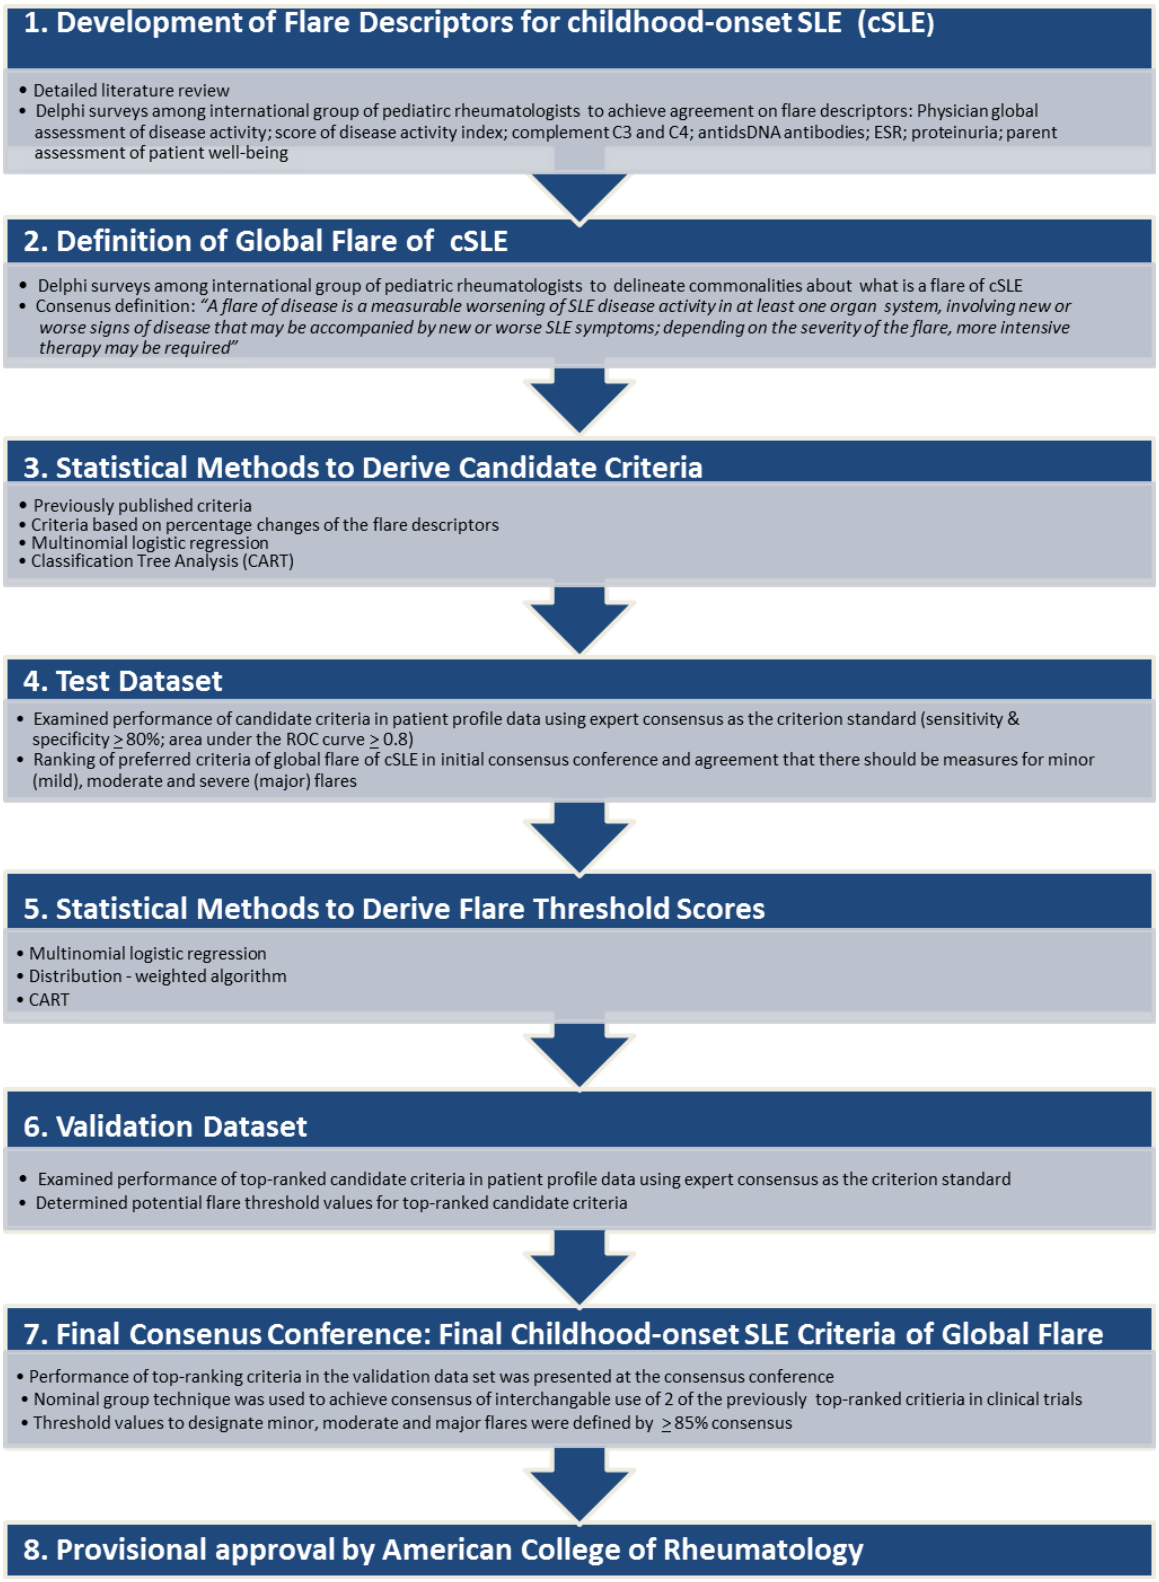
Submitted for publication July 8, 2017; accepted in revised form March 8, 2018.



1. Development of Flare Descriptors for childhood-onset SLE (cSLE)
• Detailed literature review
• Delphi surveys among international group of pediatirc rheumatologists to achieve agreement on flare descriptors: Physician global assessment of disease activity; score of disease activity index; complement C3 and C4; antidsDNA antibodies; ESR; proteinuria; parent assessment of patient well-being
2. Definition of Global Flare of cSLE
• Delphi surveys among international group of pediatric rheumatologists to delineate commonalities about what is a flare of cSLE
• Consenus definition: "A flare of disease is a measurable worsening of SLE disease activity in at least one organ system, involving new or worse signs of disease that may be accompanied by new or worse SLE symptoms; depending on the severity of the flare, more intensive therapy may be required"
3. Statistical Methods to Derive Candidate Criteria
• Previously published criteria
• Criteria based on percentage changes of the flare descriptors
• Multinomial logistic regression
• Classification Tree Analysis (CART)
4. Test Dataset
• Examined performance of candidate criteria in patient profile data using expert consensus as the criterion standard (sensitivity & specificity ≥ 80%; area under the ROC curve ≥ 0.8)
• Ranking of preferred criteria of global flare of cSLE in initial consensus conference and agreement that there should be measures for minor (mild), moderate and severe (major) flares
5. Statistical Methods to Derive Flare Threshold Scores
• Multinomial logistic regression
• Distribution - weighted algorithm
• CART
6. Validation Dataset
• Examined performance of top-ranked candidate criteria in patient profile data using expert consensus as the criterion standard
• Determined potential flare threshold values for top-ranked candidate criteria
7. Final Consenus Conference: Final Childhood-onset SLE Criteria of Global Flare
• Performance of top-ranking criteria in the validation data set was presented at the consensus conference
• Nominal group technique was used to achieve consensus of interchangable use of 2 of the previously top-ranked critieria in clinical trials
• Threshold values to designate minor, moderate and major flares were defined by ≥ 85% consensus
8. Provisional approval by American College of Rheumatology

Figure 1. Flow diagram of the entire process used to develop and validate the approved criteria of global flare of cSLE. Steps 1–5 have been summarized in references 5 and 14. The current study begins at step 5 and focuses on steps 6–8. antidsDNA = anti–double-stranded DNA; ESR = erythrocyte sedimentation rate; ROC = receiver operating characteristic curve.

and score = 1 if otherwise). Similar to algorithms derived by multinomial logistic regression, CART-based criteria yield "CART-scores" that can be used to decide on the presence of a flare, including its severity (14).

Step A: PPs and ratings of disease course of a PP. Two of the authors (HIB and MH) conducted a pilot study to test the format of the PP. Built on this pilot study, we generated over 2,996 unique PPs, using prospectively collected data of cSLE patients from the Cincinnati Children's Hospital Medical Center Lupus Registry (18), the Paediatric Rheumatology International Trials Organisation Lupus Cohort (19), the UK Juvenile-Onset SLE Cohort Study (20), and the Atherosclerosis Prevention in Pediatric Lupus Erythematosus (APPLE) trial (21). Missing observations in the data sets were imputed using multiple imputation methods and expectation–maximization algorithms in computation (22–24).

Each PP provided data about a patient at the time of a baseline visit and a followup visit. For each PP visit, the cSLE flare descriptors were provided (5) as follows: 1) MD-global, measured on a visual analog scale (VAS; 0 = inactive disease, 10 = very active disease); 2) parent assessment of patient overall well-being, measured on a VAS with a range from 0 to 10 (0 = very poor, 10 = very well); 3) proteinuria, measured by timed urine collection or spot PCR; 4) ESR; 5) levels of complement C3 and C4; and 6) item and summary scores of the SLEDAI-2K (7), or the domain and summary scores of the BILAG using the following numeric conversion: A = 12, B = 8, C = 1, and D/E = 0 (8). Information on complete blood counts and differential, serum chemistry, urinalysis, and anti–double-stranded DNA antibodies were also provided. Details on PP formats for the SLEDAI and BILAG are provided in Supplementary Appendices A and B, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23557/abstract.

PP raters were randomly assigned to assess the disease course of a maximum of 51 PPs. Response options offered were major flare, moderate flare, minor flare, unchanged, improved, or "I do not have enough information to make this assessment." A global flare was considered as "present" whenever the disease course was rated as minor, moderate, or major flare.

Step B: adjudication of disease course of the PP. A randomization scheme was preplanned to ensure that each PP was sent to about 13 raters, with the ratio of American and international raters matching that of the PP raters' pool (about 1:1). PPs with fewer than 4 ratings were regarded as "invalid" or "unqualified" and excluded from further consideration. Only "qualified" PPs with successful adjudication were considered in step 3.

Given that PP raters may not necessarily agree on the disease course, the "true" overall course of cSLE for a given PP was adjudicated using 2 approaches: 1) 67% rule: at least two-thirds of the raters agreed on a given disease course, and 2) majority-rule: the majority of the raters of a PP agreed on a given disease course. Other rules (50% rule and 75% rule) were also explored, and results were similar to the majority-rule and the 67% rule, respectively; therefore, they are not presented herein.

Step C: assessment of performance. *Statistical analysis in preparation of the testing of preliminary flare criteria.* Considering the intended widespread use of the cSLE flare criteria (14), we tested whether there were systematic differences in the ratings provided by raters from 1) different geographic regions or 2) with varying professional experience as measured by the duration of medical practice. Agreement among raters was assessed using intraclass correlation coefficients (ICCs) and/or kappa (κ) statistics. An ICC or a kappa value can be interpreted as follows: poor agreement: ICC or $\kappa < 0.4$, fair to good agreement: ICC or $\kappa \geq 0.4$–0.75, and substantial to excellent agreement: ICC or $\kappa > 0.75$ (25).

Performance and accuracy. Each of the 4 flare algorithms (SLEDAI-based criteria, BILAG-based criteria, SLEDAI-CART, and BILAG-CART) was assessed for diagnostic accuracy using receiver operating characteristic (ROC) curve analysis. Specifically, the area under the ROC curve (AUC) was calculated, and the diagnostic accuracy was considered outstanding, excellent, good, fair, and poor if the AUC was in the range of 0.9–1.0, 0.81–0.90, 0.71–0.80, 0.61–0.70, and <0.60, respectively (14,26). In contrast to the flare criteria derived from multinomial regression models (SLEDAI- and BILAG-based criteria), CART-based flare algorithms (SLEDAI-CART and BILAG-CART) result in a single discrete value for sensitivity and specificity, respectively. Considering all possible flare scores, the overall diagnostic accuracy of an algorithm can be estimated.

Threshold score candidates for algorithms derived by multinomial logistic analysis. In the absence of strong guidance from the ACR, we used 2 statistical methods to define potential threshold scores. First, in an earlier phase of the project, consensus had been achieved that "flare score threshold" for a given algorithm should reflect the highest conditional AUC among all candidate thresholds on a ROC curve. Hence, these flare score thresholds represent the point on the ROC curves with the highest precision of correctly classifying the severity of a cSLE flare. Second, we also explored a distribution-weighted approach in which the flare score threshold was calculated based upon the average of means of scores in 2 neighboring flare states weighted by the SDs of the scores. The performance of the candidate thresholds from both statistical analyses described above was calculated, as well as average accuracies for the correct identification of minor, moderate, and major flares for the SLEDAI-based and BILAG-based algorithms.

Step D: ranking of candidate flare criteria and thresholds score. To support decision making, consensus conference participants reviewed a syllabus that provided the results of the preceding Delphi surveys, relevant published medical literature, and the results of the statistical analyses prior to the consensus conference (see step 3). Participants in the consensus conference were 13 experienced pediatric rheumatologists and nephrologists from South America, North America, Asia, and Europe with substantial clinical and research experience in cSLE (HIB, MWB, SPA, SA, CAS, FF, BG, SEW, DML, AR, RK, TA, and MKG).

A priori, the consensus level at the consensus conference was set at 75%, i.e., comparable or even somewhat higher than that chosen for similar studies in the past (15–18).

Using nominal group technique guided by an experienced moderator (BMF), the expert panel assessed each of the 4 top candidate flare algorithms (14) and potential flare score thresholds according to 1) feasibility (i.e., practicability: can the items be measured easily?), 2) reliability (i.e., reproducibility: can the items be measured precisely?), 3) redundancy (are there 2 or more items included in the candidate criteria measuring the same aspect of the disease?), 4) face validity (i.e., credibility: are the criteria sensible?), 5) content validity (i.e., comprehensiveness: do the criteria sample all of the domains of the disease?), 6) criterion validity: based on AUC, do the criteria accurately approximate the gold standard? (i.e., the adjudicated disease course as per the 67% rule or majority-rule), 7) sensitivity and specificity (do the criteria effectively identify patients with cSLE flares and distinguish them from patients who do not have a flare of their cSLE?), and 8) discriminant validity: do the criteria detect the smallest clinically important change? (i.e., discriminate patients with 1 of the following disease courses: minor flare, moderate flare, major flare, or no flare). Based on the above considerations, the consensus conference experts were asked to rank the candidate flare criteria from 1 (lowest criterion) to 4 (highest criterion).

The survey source data were batch processed, and open-source online survey software, LimeSurvey, was used for response management and as a presentation layer (see http://www.limesurvey.org/). All analyses were done using SAS, version 9.4, software and SYSTAT 12 software. *P* values less than 0.05 were considered statistically significant.

Table 1. Baseline characteristics of validation cohort*

	Majority rule (n = 1,860)	67% rule (n = 818)
Mean age, years	15.0	15.1
Female sex, %	81.7	82.5

* Values presented are changes in means ± SDs, adjusted for multiple comparisons using the Tukey's method, unless indicated otherwise. cSLE = childhood-onset systemic lupus erythematosus; ESR = erythrocyte sedimentation rate; MD-global = physician global assessment of disease activity; SLEDAI = Systemic Lupus Erythematosus Disease Activity Index; BILAG = British Isles Lupus Assessment Group.

RESULTS

PP raters and validation data set (steps A and 2). A total of 2,996 ratings were provided to 503 pediatric rheumatologists and used for step 2. The response rate of the pediatric rheumatologists to the PP was 54% (274 of 503; locations: 30% from the US and Canada, 8% from Australia/Asia, 3% Africa/Middle East, 40% South and Central America, and 19% from Europe). The majority (69%) of PP raters had over 10 years of experience in treating cSLE. There were 1,860 PPs (1,860 of 2,996 [62%]) that were rated by at least 4 raters and therefore considered "qualified" for inclusion in step 3. There were no significant differences of distribution of flares between qualified and unqualified PPs ($P = 0.62$ by Fisher's exact test).

When the majority rule was applied to the "qualified" PPs, there were 1,318 PPs representing global flares (510 minor flares, 483 moderate flares, and 325 major flares) and 542 unchanged/improved (29% of 1,860 PPs). When applying the 67% rule to the 1,860, only 818 PPs remained available for analysis, among them 484 representing a flare (194 minor flares, 146 moderate flares, and 144 major flares) and 334 PPs without cSLE flare. The patient characteristics reflected in these PPs are summarized in Table 1. PP raters from different geographic locations did not differ systematically in the disease course assignment for a given PP (North America versus other countries: ICC 0.658). Similarly, there was fair to good agreement among PP raters with different duration of medical experience (3–5, 6–10, 10–15, and >15 years) for the interpretation of the disease courses (ICC 0.656). Additionally, we explored other selection criteria (50% rule, 75% rule) and found no systematic differences with the 50% rule and 75% rule, resulting in similar adjudication of the PP compared to the majority-rule and the 67% rule, respectively (data not shown).

Performance of preliminary algorithms of cSLE global flares (step C). The absolute baseline-to-followup changes of the parameters considered in the preliminary flare algorithms by flare severity and rule are provided in Table 2. Irrespective of the data set (67% rule, majority-rule), most of the cSLE flare descriptors included in the preliminary cSLE flare criteria (ESR, PCR, MD-global, SLEDAI, and BILAG) significantly changed between the baseline and followup visit, by flare severity. Notably, the accuracy of the SLEDAI-based algorithm was outstanding (AUC 0.93, 95% confidence interval [95% CI] 0.91–0.95), as was that of the BILAG-based algorithm (AUC 0.93, 95% CI 0.89–0.98). The CART-SLEDAI algorithm had an excellent accuracy for identifying patients with global flare of cSLE (any severity) (AUC 0.89, sensitivity 88.8%, and specificity 87.1%). The same was true for the CART-BILAG criteria (AUC 0.84, sensitivity 93.9%, and specificity 72.9%). Comparisons of accuracies in the development data set in 2010 (18) and this validation data set are summarized in Table 3.

Figure 2A and B depict potential thresholds for defining minor, moderate, and major flares. In this final consensus conference, again consensus (100%) was reached to use the statistically optimal threshold from logistic models to define all threshold scores for the both SLEDAI-based and the BILAG-based algorithms. As shown in Figure 3A and B, using these threshold cutoff scores allows for the discrimination of minor from moderate or severe flares, all with sensitivities and specificities of ≥82%. Neither of the CART-based algorithms was suited

Table 3. Comparison of the performance of the preliminary flare algorithm in the development and validation data set*

			AUC	
	Algorithm	Flare category	2010 data	2017 data
SLEDAI-based flare score†	Score = 0.5 × SLEDAI + 0.45 × PCR + 0.5 × MD + 0.02 ESR	Major flare	0.95	0.93
		At least moderate flare	0.85	0.94
		At least minor flare	0.86	0.93
BILAG-based flare score†	Score = 0.4 × BILAG + 0.65 × PCR + 0.5 × MD + 0.02 ESR	Major flare	0.93	0.91
		At least moderate flare	0.85	0.92
		At least minor flare	0.85	0.93
SLEDAI-based CART rule	Score = 4 if 3 ≤ SLEDAI	Major flare	0.85	0.76
	Score = 3 if 0.7 ≤ PCR and 3 > SLEDAI	At least moderate flare	0.80	0.80
	Score = 2 if 2 ≤ MD and 0.7 > PCR and 3 > SLEDAI	At least minor flare	0.84	0.89
	Score = 1 if otherwise			
BILAG-based CART rule	Score = 4 if 2 ≤ BILAG	Major flare	0.86	0.71
	Score = 3 if 0.7 ≤ PCR and 2 > BILAG	At least moderate flare	0.80	0.75
	Score = 2 if 2 ≤ MD and 0.7 > PCR and 2 > BILAG	At least minor flare	0.82	0.84
	Score = 1 if otherwise			

* Values presented represent the area under the receiver operating characteristic curve (AUC) considering patient profile (PP) with consensus as defined by the 67% rule. Numeric values larger than or equal to the flare score signify a flare; higher scores are seen with more severe flare. See reference 14 for details about algorithm development. SLEDAI = Systemic Lupus Erythematosus Disease Activity Index; PCR = urine protein/creatinine ratio from random urine sample; MD = physician global assessment of disease measured on a visual analog scale (range 0–10, where 0 = inactive disease); ESR = erythrocyte sedimentation rate; BILAG = British Isles Lupus Assessment Group; CART = classification tree analysis.
† Algorithm considers for the change (baseline – followup) of each of the flare descriptors included.

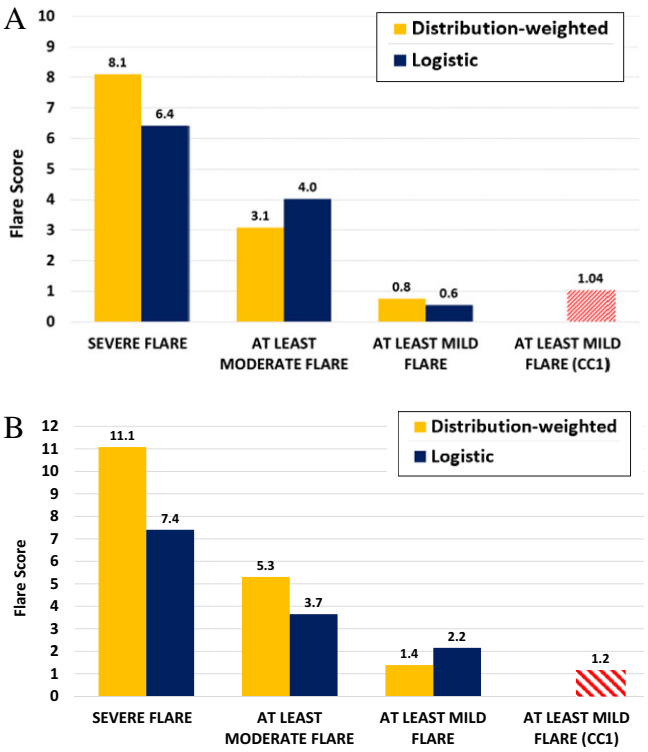

Figure 2. Potential flare thresholds to define childhood-onset systemic lupus erythematosus flare severity. **A**, Systemic Lupus Erythematosus Disease Activity Index–based algorithm, **B**, British Isles Lupus Assessment Group–based algorithm. Flare threshold values based on multinomial logistic regression models (blue bars) and distribution-weighted strategies (yellow bars) for each flare category (minor, moderate, major flare) were presented to the experts participating in the final consensus conference. There was 100% agreement to use threshold values derived from multinomial logistic regression, i.e., thresholds with the best statistical performance in receiver operating characteristic (ROC) curve analysis. Each threshold had the largest summation of sensitivity and specificity on the ROC curve. Red bars indicate the scores using each algorithm to assess the 2010 data (14). CC1 = Threshold value for flare as agreed upon in the initial consensus conference (see Step 4, Figure 1).

to discriminate between mild and moderate cSLE flares (Figure 3C and D).

Ranking of the preliminary cSLE flare algorithms (step D). Consensus conference participants achieved consensus that the BILAG-based (92%) and SLEDAI-based (100%) flare algorithms both have construct validity for measuring global flares of cSLE. There was consensus (100%) to recommend that both measures be collected in future cSLE clinical trials and that either one may be chosen as the primary end point. Consistent with their performance in the validation data set, no consensus was reached whether one of these 2 algorithms was preferable to the other. Consensus was achieved that CART-based algorithms are not suited for use in clinical trials, given that these algorithms cannot be used to discriminate minor from moderate cSLE flares. The results of this study were reviewed by the ACR Criteria Subcommittee and the ACR Quality of Care Committee.

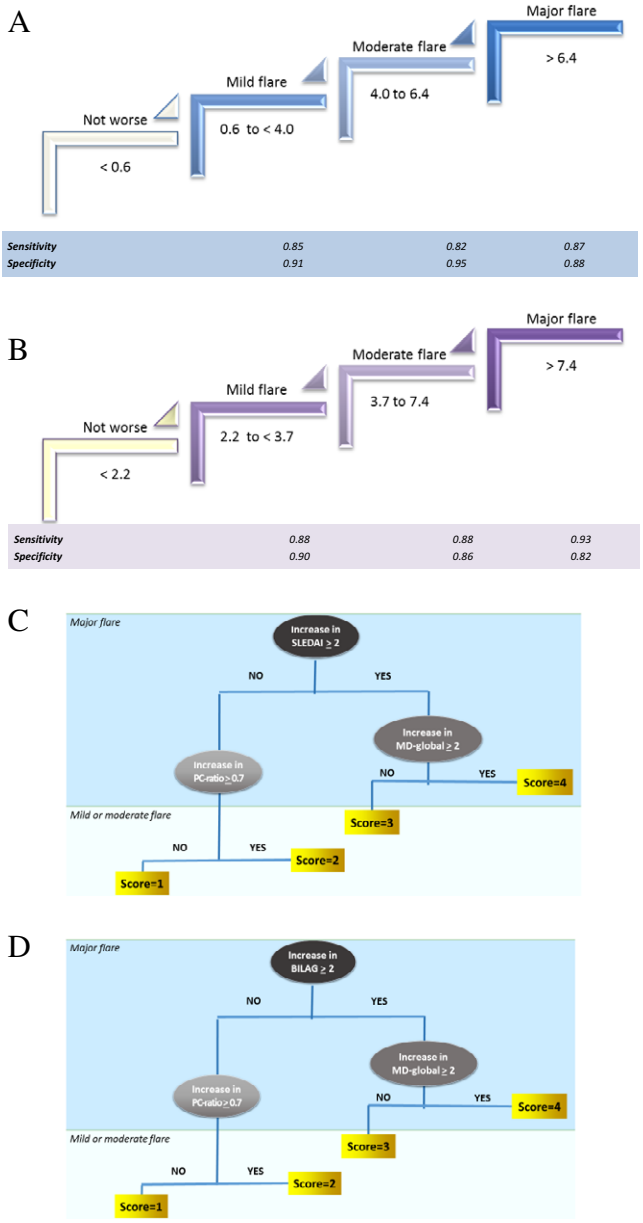

Figure 3. Flare score interpretation. Flare scores represent the cutoff score on the receiver operating characteristic curves that provide the best discrimination between adjacent disease states (no flare, minor or mild flare, moderate flare, major or severe flare) with childhood-onset systemic lupus erythematosus (cSLE). Sensitivities and specificities are shown for the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI)–based algorithm (**A**) and the British Isles Lupus Assessment Group (BILAG)–based algorithm (**B**). The SLEDAI–classification tree analysis (CART) algorithm (**C**) (where score = 4 if 3 ≤ SLEDAI, score = 3 if 0.7 ≤ protein/creatinine ratio [PC-ratio] and 3 > SLEDAI, score = 2 if 2 ≤ physician global assessment [MD-global] and 0.7 > PC-ratio and 3 > SLEDAI, and score = 1 if otherwise) and in the BILAG-CART algorithm (**D**) (where score = 4 if 2 ≤ BILAG, score = 3 if 0.7 ≤ PC-ratio and 2 > BILAG, score = 2 if 2 ≤ MD-global and 0.7 > PC-ratio and 2 > BILAG, and score = 1 if otherwise) are only able to distinguish major flares from other cSLE disease courses. Thus, the other 2 of the top preliminary flare criteria (SLEDAI-CART, BILAG-CART) were unable to discriminate minor from moderate cSLE flare.

DISCUSSION

The need to develop internationally agreed upon criteria for disease flares has become more urgent since the introduction of randomized withdrawal trials in pediatric rheumatology, in which time to flare or the proportion of patients who experience a flare are used as primary efficacy measures (27). We confirm the outstanding accuracy of the previously developed preliminary criteria of global flares of cSLE, based on large international data sets used for validation. Consensus has been achieved on how to interpret flare scores. The preferred cSLE global flare algorithms for use in clinical trials were derived from multinomial logistic regression models. These algorithms consider the differential and complementary contribution of select cSLE flare descriptors in identifying disease flares in this disease with highly variable multiorgan involvement. Despite consensus that CART-based algorithms are potentially of value when used in clinical care settings, there was agreement that they should not be used in clinical trials. As for SLE in adulthood, measures of the overall course are especially relevant because not all cSLE features improve or worsen in parallel. Current drugs used in cSLE therapy are not equally effective in reducing disease activity in the various organ systems. Thus, it is reasonable to assume that the same holds true for new or emerging drugs for cSLE. In clinical trials aimed at reducing cSLE-mediated inflammation in certain organ systems, it appears mandatory to ensure that global disease, i.e., disease manifestations in other than the target organ systems, is not worsening. The results of this study support that the SLEDAI-based and the BILAG-based flare scores are both highly suited to provide such information.

Based on the current evidence about these algorithms, they are similarly sensitive, specific, and accurate. Hence, consensus conference experts considered both algorithms equally valuable and suitable for use in clinical trials. Different from what is currently used to gauge response to therapy in juvenile idiopathic arthritis (11), flare algorithms derived from regression models allow for consideration of the differential importance of changes in individual cSLE flare descriptors when recognizing cSLE flares. The SLEDAI-based and BILAG-based flare scores are reminiscent of the Disease Activity Score (DAS) used in rheumatoid arthritis (28). However, the DAS considers the natural logarithm of the ESR and square roots of the number of swollen or tender joints, while the preliminary cSLE flare criteria require at most simple arithmetic maneuvers to calculate a cSLE flare score, supporting their ease of use (14).

All flare score algorithms consider changes in proteinuria, despite the inclusion of proteinuria assessment in the SLEDAI and BILAG scores. This allows for detection of renal SLE flares that occur in patients with existing proteinuria and also allows for the consideration of increases in proteinuria that would otherwise not be captured given the item definition used in the SLEDAI and BILAG, respectively. As reported previously, exclusion of changes in proteinuria from the flare algorithms resulted in inferior accuracy in predicting cSLE flares (14).

In line with our earlier studies (5,8), both cSLE flare criteria from CART and multinomial logistic regression analysis showed excellent or even outstanding accuracy. Statistically, they were superior to algorithms that considered equally weighted percentage changes from a statistical point of view in the past.

Given the simplicity of CART-based criteria, they appear particularly suited for clinical settings, but a potential shortcoming of CART-based criteria includes so-called "over-fitting of the mathematical model," which can make them prone to less favorable statistical performance in subsequent validation studies (14). Mild cSLE flares often do not prompt clinicians to change therapy, whereas moderate cSLE flares generally require more intensive antiinflammatory therapy. Although CART-based flare algorithms were highly accurate for discriminating any kind of global flare when tested in this validation data set, they were unable to distinguish minor from moderate cSLE flares. This limitation prompted the agreement among the consensus conference experts to not recommend CART-based algorithms for use as outcome measures in clinical trials.

We chose 2 approaches to adjudicate the disease course (67% rule, majority rule) presented in the various PPs, which might have introduced bias. However, both approaches yielded comparable results.

The ACR has outlined a series of validation steps necessary before new criteria are to be widely used for clinical care or research (12). Among others, one step is to use data from clinical trials for developing response criteria. However, clinical trial data from interventions that impact cSLE activity are unavailable at present. In our study, the presence of a flare was based on the PP raters' perception of the course of cSLE instead. Given their prospective character and the expertise of the PP raters, we consider the quality of our data to be high, and the number of PPs per flare severity category yielded robust provisional cSLE flare criteria.

We would like to point out that PP raters from different parts of the world and different degrees of experience all showed excellent concordance (interrater agreement) in their assessment of the cSLE course. This supports the robustness of this validation study. A limitation might be that only 54% of those physicians approached to provide PP ratings provided feedback. Nonetheless, responses from 274 pediatric rheumatologists were obtained, which is a much larger number than for many similar validation exercises (9–11).

In addition to criteria for global flare and improvement, criteria for changes of cSLE in specific organ systems are likely needed. Depending on the proposed effect of a cSLE drug candidate, the Cutaneous Lupus Activity and Severity Index (29), pediatric lupus nephritis response measures (30), and standardized joint assessments for children (11) have already been validated to adequately capture the proposed therapeutic effects. To further provide support for the accuracy of the provisional criteria of global flare of cSLE, data from clinical trials will be needed.

Taken together, a methodologically stringent validation process has been employed to calculate a flare score that can be used to interpret the course of cSLE over time with respect to the degree of worsening that might have occurred. Based on the data available, these algorithms cannot be used to quantify potential improvement over time.

ACKNOWLEDGMENTS

We thank Kasha Wiley (overall study coordination), Susan Priest (consensus conference logistics), Pinar Avar (consensus conference support and data management), and Carly Muller, Malea Rolfsen, Allen Watts, Gaurav Gulati, and Jamie Meyers-Eaton (patient profile testing) from Cincinnati Children's Hospital Medical Center (CCHMC), as well as CCHMC Biomedical Informatics (web-based data management application development). We also thank Drs. Laura Schanberg and Christy Sandberg and the Childhood Arthritis and Rheumatology Research Alliance for provision of the data from the Atherosclerosis Prevention in Pediatric Lupus Erythematosus clinical trial, as well as the UK Juvenile-Onset SLE (JSLE) Study Group, for provision of the data from the UK JSLE Cohort Study. We are indebted to the members of the External Scientific Advisory Committee of this study for their advice in the study implementation, conduction, and its statistical analysis: Drs. Tuhina Neogi, Ian Bruce, David Isenberg, Nicola Ruperto, and James Witter. For a list of physicians who made important contributions to this work by providing their expertise when rating the patient profiles, see Supplementary Appendix C, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23557/abstract.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be submitted for publication. Dr. Brunner had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception and design. Brunner, Holland, Beresford, Ardoin, Appenzeller, Silva, Flores, Goilav, Wenderfer, Levy, Ravelli, Khunchandani, Avcin, Klein-Gitelman, Feldman, Ruperto, Ying.

Acquisition of data. Brunner, Holland, Beresford, Ardoin, Appenzeller, Silva, Flores, Goilav, Wenderfer, Levy, Ravelli, Khunchandani, Avcin, Klein-Gitelman, Feldman, Ruperto, Ying.

Analysis and interpretation of data. Brunner, Holland, Beresford, Ardoin, Appenzeller, Silva, Flores, Goilav, Wenderfer, Levy, Ravelli, Khunchandani, Avcin, Klein-Gitelman, Feldman, Ruperto, Ying.

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the physician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions, and drug formularies or other third-party analyses that cite ACR guidelines should state this. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The ACR is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To provide recommendations for the management of juvenile idiopathic arthritis (JIA) with a focus on nonpharmacologic therapies, medication monitoring, immunizations, and imaging, irrespective of JIA phenotype.

Methods. We developed clinically relevant Patient/Population, Intervention, Comparison, and Outcomes questions. After conducting a systematic literature review, the Grading of Recommendations Assessment, Development and Evaluation approach was used to rate the quality of evidence (high, moderate, low, or very low). A Voting Panel including clinicians and patients/caregivers achieved consensus on the direction (for or against) and strength (strong or conditional) of recommendations.

Results. Recommendations in this guideline include the use of physical therapy and occupational therapy interventions; a healthy, well-balanced, age-appropriate diet; specific laboratory monitoring for medications; widespread use of immunizations; and shared decision-making with patients/caregivers. Disease management for all patients with JIA is addressed with respect to nonpharmacologic therapies, medication monitoring, immunizations, and imaging. Evidence for all recommendations was graded as low or very low in quality. For that reason, more than half of the recommendations are conditional.

Conclusion. This clinical practice guideline complements the 2019 American College of Rheumatology JIA and uveitis guidelines, which addressed polyarthritis, sacroiliitis, enthesitis, and uveitis, and a concurrent 2021 guideline

on oligoarthritis, temporomandibular arthritis, and systemic JIA. It serves as a tool to support clinicians, patients, and caregivers in decision-making. The recommendations take into consideration the severity of both articular and nonarticular manifestations as well as patient quality of life. Although evidence is generally low quality and many recommendations are conditional, the inclusion of caregivers and patients in the decision-making process strengthens the relevance and applicability of the guideline. It is important to remember that these are recommendations. Clinical decisions, as always, should be made by the treating clinician and patient/caregiver.

INTRODUCTION

Reflecting the changing medical landscape, the American College of Rheumatology (ACR) regularly updates clinical practice guidelines and plans to review these annually and update as needed. The process for updating the 2011 and 2013 juvenile idiopathic arthritis (JIA) guidelines (1,2) began in 2017. Important clinical topics for consideration were first identified at a meeting to define the scope of the guidelines. Advances in the treatment of JIA and better understanding of pathogenesis dictated separating this clinical practice guideline into several parts due to the breadth of topics. The first part, addressing polyarthritis, sacroiliitis, enthesitis, and uveitis, was published in 2 articles in 2019 (3,4). The second part, presented here in 2 articles, covers 1) oligoarthritis, temporomandibular joint (TMJ) arthritis, and systemic JIA, and 2) nonpharmacologic treatments, patient monitoring, immunizations, and imaging (5). The methods and literature review described below reflect the unified process used for the second part of these guidelines, including both articles.

We developed clinically relevant Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions. Using Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology, recommendations were then developed based on the best available evidence for commonly encountered clinical scenarios. Prior to final voting, input was sought from relevant stakeholders including a panel of young adults with JIA and caregivers of children with JIA to consider their values and perspectives in making recommendations. Both the patient/caregiver and guideline Voting Panels stressed the need for individualized treatment while being mindful of available evidence and the need to include recommendations on nonpharmacologic therapies.

METHODS

This guideline followed the ACR guideline development process and ACR policy guiding management of conflicts of interest and disclosures (https://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines), which include GRADE methodology (6,7), and adheres to Appraisal of Guidelines, Research and Evaluation criteria (8). Supplementary Appendix 1 (available on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract) includes a detailed description of the methods. Briefly, the Core Leadership Team (KBO, DBH, DJL, SS) drafted clinical PICO questions. PICO questions were revised and finalized based on feedback from the entire guideline development group and the public. The Literature Review Team performed systematic literature reviews for each PICO (for search terms, see Supplementary Appendix 2,

This article is published simultaneously in *Arthritis Care & Research*.

Submitted for publication March 4, 2021; accepted in revised form November 23, 2021.

https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract), graded the quality of evidence (high, moderate, low, or very low), and produced the evidence report (Supplementary Appendix 3, https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract). It should be noted that GRADE methodology does not distinguish between lack of evidence (i.e., none) and very low–quality evidence. The Core Team defined multiple critical study outcome(s) for PICOs relevant to each JIA phenotype (Supplementary Appendix 4, https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract).

A panel of 15 members, including young adults with JIA and caregivers of children with JIA, met virtually (moderated by the principal investigator [KBO]), reviewed the evidence report, and provided input to the Voting Panel. Two members of this panel were also members of the Voting Panel to ensure that the patient voice was part of the entire process. The Voting Panel reviewed the evidence report and patient/caregiver perspectives and then discussed and voted on recommendation statements. Consensus required ≥70% agreement on both direction (for or against) and strength (strong or conditional) of each recommendation, as per ACR practice. A recommendation could be either in favor of or against the proposed intervention and either strong or conditional. According to GRADE, a recommendation is categorized as strong if the panel is very confident that the benefits of an intervention clearly outweigh the harms (or vice versa); a conditional recommendation denotes uncertainty regarding the balance of benefits and harms, such as when the evidence quality is low or very low, or when the decision is sensitive to individual patient preferences, or when costs are expected to impact the decision. Thus, conditional recommendations refer to decisions in which incorporation of patient preferences is a particularly essential element of decision-making. Examples of each class of intervention addressed in the recommendations are shown in Table 1. Rosters of the Core Leadership Team, Literature Review Team, and both panels are included in Supplementary Appendix 5 (https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract).

Table 1. Classes of interventions

Nonsteroidal antiinflammatory drugs	Any at therapeutic dosing (ibuprofen, naproxen, tolmetin, indomethacin, meloxicam, nabumetone, diclofenac, piroxicam, etodolac, celecoxib)
Conventional synthetic disease-modifying antirheumatic drugs	Methotrexate, sulfasalazine, hydroxychloroquine, leflunomide, calcineurin inhibitors (cyclosporin A, tacrolimus)
Biologic disease-modifying antirheumatic drugs	Tumor necrosis factor inhibitors (adalimumab, etanercept, infliximab, golimumab, certolizumab pegol); other biologic response modifiers (abatacept, tocilizumab, anakinra, canakinumab)
Targeted synthetic disease-modifying antirheumatic drugs	JAK inhibitor (tofacitinib)
Glucocorticoids	Oral (any); intravenous (any); intraarticular (triamcinolone acetonide, triamcinolone hexacetonide)
Immunizations	Live attenuated; inactivated
Nonpharmacologic therapies	Physical therapy; occupational therapy; dietary changes; herbal supplements

Guiding principles

The development of the recommendations presented herein was guided by the following principles:

1. Consistent with the ACR's 2019 JIA guidelines, these recommendations are for persons already diagnosed as having JIA.
2. Coexisting extraarticular conditions that would influence disease management and monitoring, such as uveitis, psoriasis, or inflammatory bowel disease, are not addressed within these guidelines.
3. Recommendations for immunizations were evaluated to be consistent with guidelines from the American Academy of Pediatrics (AAP) and the Advisory Committee on Immunization Practices (ACIP) while taking into consideration the unique needs of persons with JIA.
4. Recommendations are intended to be used by all clinicians caring for persons with JIA.
5. Shared decision-making with families and patients is critical.

RESULTS/RECOMMENDATIONS

The initial literature review (through August 7, 2019) identified 4,308 articles in searches for all PICO questions pertaining to oligoarthritis, TMJ arthritis, systemic JIA, and the topics addressed in this report, including nonpharmacologic therapies, nutrition, supplements, medication monitoring, immunizations, and imaging. A July 9, 2020 search update identified 367 more references, for a total of 4,675 articles after duplicates and non-English publications were removed. After exclusion of 2,291 titles and abstracts, 2,384 full-text articles were screened. Of these, 1,939 were excluded (Supplementary Appendix 6, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract), leaving 445 articles to be considered for the evidence report. Ultimately, 336 articles were matched to PICO questions and included in the final evidence report. Quality of evidence was uniformly low or very low; 17 PICO questions lacked any associated evidence and, as per GRADE methodology, were categorized as very low (Tables 2–6). The recommendations that follow are based on 62 PICO questions. Several PICO questions were split into 24 sub-PICO questions to

Table 2. Strength of recommendations and quality of supporting evidence

Topic	Strength of recommendation			Quality of supporting evidence			
	No. of recommendations	Conditional	Strong	Very low	Low	Moderate	High
Nonpharmacologic therapies	4	2	2	4	0	0	0
Medication monitoring*	20	17	3	17	0	0	0
Infection surveillance/immunizations	7	3	4	5	2	0	0
Imaging	2	1	1	2	0	0	0
Total	33	23	10	28	2	0	0

* Lack of evidence for tofacitinib given the US Food and Drug Administration approval date.

improve specificity. Nine questions initially posed were discarded by the Voting Panel because of redundancy or lack of relevance. Final recommendations are described below and in Tables 3–6, which include reference(s) to which PICO question(s) in the evidence report correspond to the recommendation statement.

Nonpharmacologic therapies (Table 3)

Patient/caregiver panelists specifically asked that recommendations for nonpharmacologic treatment be included in this guideline, although they understood that evidence to support specific statements is generally lacking.

Physical and occupational therapy (PT/OT)

PT and OT are conditionally recommended regardless of concomitant pharmacologic therapy.

Reasons for using PT or OT include maintaining or improving joint range of motion (particularly for contractures), improving strength, reversing functional deficits, improving endurance, preventing injury, and promoting improved participation in activities of daily living, family routines, and occupations (9,10).

Nutrition

A discussion of healthy, age-appropriate diet is strongly recommended.

Use of a specific diet to treat JIA is strongly recommended *against*.

Ample evidence supports the value of a healthy, balanced, nutrient-dense diet for all children, with consideration of specific age-appropriate nutritional requirements (e.g., fat, calcium)

Table 3. Nonpharmacologic therapies*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
A discussion of healthy, age-appropriate diet is **strongly** recommended.	Very low	PICO 7. In children with oligoarticular JIA, should dietary or herbal interventions be recommended, in addition to whatever other therapeutic options are given, versus not recommending them?	48–49
Use of a specific diet to treat JIA is **strongly** recommended *against*.	Very low	PICO 7. In children with oligoarticular JIA, should dietary or herbal interventions be recommended, in addition to whatever other therapeutic options are given, versus not recommending them?	48–49
Use of supplemental or herbal interventions specifically to treat JIA is **conditionally** recommended *against*.	Very low	PICO 17. In children with JIA with active TMJ arthritis, should dietary or herbal interventions be recommended, in addition to whatever other therapeutic options are given, versus not recommending them?	60
Physical and occupational therapy are **conditionally** recommended regardless of concomitant pharmacologic therapy.	Very low	PICO 8. In children with oligoarticular JIA, regardless of disease activity and poor prognostic features, should PT/OT versus no PT/OT (regardless of concomitant medical therapy) be recommended?	49–51
		PICO 18. In children with JIA with active TMJ arthritis, regardless of disease activity and poor prognostic features, should PT versus no PT (regardless of concomitant medical therapy) be recommended?	60

* PICO = Patient/Population, Intervention, Comparison, and Outcomes; JIA = juvenile idiopathic arthritis; TMJ = temporomandibular joint; PT = physical therapy; OT = occupational therapy.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract.

Table 4. Medication monitoring*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
NSAIDs: Monitoring via CBC counts, LFTs, and renal function tests every 6–12 months is **conditionally** recommended.	Very low	PICO 30. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel, and urinalysis) for children receiving long-term daily NSAID treatment?	144–145
MTX: Monitoring via CBC counts, LFTs, and renal function tests within the first 1–2 months of usage and every 3–4 months thereafter is **strongly** recommended.	Very low	PICO 31. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel) for children being treated with MTX (oral or subcutaneous)?	145–150
Decreasing the MTX dosage or withholding MTX is **conditionally** recommended if a clinically relevant elevation in LFT results or decreased neutrophil or platelet count is found.	Very low	PICO 32. After MTX (oral or subcutaneous) is initiated, is there a recommended medication change in response to elevated LFT results and decreased neutrophil or platelet count?	150–153
Use of folic/folinic acid in conjunction with MTX is **strongly** recommended.	Very low	PICO 7. In children with oligoarticular JIA, should dietary or herbal interventions be recommended, in addition to whatever other therapeutic options are used, versus not recommending them?	60
SSZ: Monitoring via CBC counts, LFTs, and renal function tests within the first 1–2 months of usage and every 3–4 months thereafter is **conditionally** recommended.	Very low	PICO 33. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel) for children with JIA being treated with SSZ?	153–155
Decreasing the SSZ dosage or withholding SSZ is **conditionally** recommended if a clinically relevant elevation in LFT results or decreased neutrophil or platelet count is found.	Very low	PICO 34. After SSZ is initiated, is there a recommended medication change in response to elevated LFT results and decreased neutrophil or platelet count?	155–157
LEF: Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3-4 months thereafter is **conditionally** recommended.	Very low	PICO 35. Should children with JIA receiving LEF have serum creatinine testing, urinalysis, CBC count, and LFTs before and during treatment, per manufacturer's recommendations?	157–158
Altering LEF administration is **conditionally** recommended if a clinically relevant elevation in LFT results occurs (temporary withholding of LEF if the ALT level is >3 times the upper limit of normal [ULN]), as per the package insert.	Very low	PICO 36. After LEF is initiated, should medication dosage be altered according to the package insert in response to elevated LFT results?	158–159
Baseline and annual retinal screening after starting HCQ are **conditionally** recommended.	Very low	PICO 37. Should children with JIA receiving treatment with HCQ have annual screening tests with automated visual fields, if age appropriate, plus spectral-domain optical coherence tomography, versus starting annual screening 5 years after treatment initiation?	159
HCQ: Monitoring via CBC counts and LFTs annually is **conditionally** recommended.	Very low	PICO 38. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel) for children with JIA being treated with HCQ?	159
TNFi: Monitoring via CBC counts and LFTs annually is **conditionally** recommended.	Very low	PICO 39. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel, and urinalysis) for children with JIA receiving TNFi treatment?	160–161
Abatacept: Doing no routine laboratory monitoring is **conditionally** recommended.	Very low	PICO 40. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel, and urinalysis) for children with JIA receiving abatacept treatment?	161–162
Tocilizumab: Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is **conditionally** recommended. Monitoring of lipid levels every 6 months is **conditionally** recommended, as per the package insert.	Very low	PICO 41. Should children with JIA receiving tocilizumab have serum creatinine testing, urinalysis, CBC count, and LFTs before and during treatment, per manufacturer's recommendations?	162

(Continued)

Table 4. (*Cont'd*)

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
Altering tocilizumab administration is **conditionally** recommended if monitoring reveals elevated LFT results (if 1–3 times the ULN, decrease the dosage or increase the interval between doses, if >3 times the ULN, withhold administration, if >5 times the ULN, discontinue treatment), neutropenia (500–1,000/mm^3), or thrombocytopenia (50,000–100,000/mm^3), as per the package insert.	Very low	PICO 42. After tocilizumab is initiated, should medication dosage be altered according to the package insert in response to elevated LFT results, neutropenia, and/or thrombocytopenia?	163
Anakinra: Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is **conditionally** recommended.	Very low	PICO 43. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel, and urinalysis) for children with JIA receiving anakinra treatment?	163–164
Canakinumab: Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is **conditionally** recommended.	Very low	PICO 44. Is there a recommended laboratory screening schedule (CBC count, comprehensive metabolic panel, and urinalysis) for children with JIA receiving canakinumab treatment?	164
Tofacitinib: Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is **conditionally** recommended. Monitoring of lipid levels 1–2 months after starting treatment is **conditionally** recommended, as per the package insert. Altering tofacitinib administration is **strongly** recommended if monitoring reveals laboratory abnormalities of concern. Specifically, medication should be discontinued if the hemoglobin level is <8 gm/dl or decreases by >2 gm/dl, or for severe neutropenia (<500/mm^3) or lymphopenia (<500/mm^3), as per the package insert.	‡	‡	‡

* PICO = Patient/Population, Intervention, Comparison, and Outcomes; NSAIDs = nonsteroidal antiinflammatory drugs; CBC = complete blood cell; LFTs = liver function tests; MTX = methotrexate; JIA = juvenile idiopathic arthritis; SSZ = sulfasalazine; LEF = leflunomide; ALT = alanine aminotransferase; ULN = upper limit of normal; HCQ = hydroxychloroquine; TNFi = tumor necrosis factor inhibitor.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract.
‡ Given recent approval for JIA and limited experience, recommendations are based on clinical trial, US Food and Drug Administration guidance, and evidence in adults.

(11,12). Therefore, it is worthwhile to address the importance of an age-appropriate diet (13). However, there is no evidence to date that supports the use of a specific diet alone to treat JIA (14,15). Furthermore, some overly restrictive diets (e.g., gluten-free, dairy-free) may result in nutritional deficits and risk of other harms (e.g., delay in treatment, cost, inconvenience).

Supplements

Use of supplemental or herbal interventions specifically to treat JIA is conditionally recommended *against*.

Voting panelists had concerns about the safety of unregulated supplements and herbal formulations and stressed the importance of discussion and transparency regarding their use. Some evidence of efficacy supports the use of supplements (e.g., fish oils) to treat joint inflammation in adults, but there are only very limited efficacy and safety data for JIA (16).

Monitoring

Medications (Tables 4 and 5)

When making decisions regarding laboratory monitoring to detect medication toxicity, the risk of adverse events and patients'/caregivers' desire for safety should be balanced with the pain, inconvenience, and cost of phlebotomy and laboratory tests. The following recommendations pertain to specific medications or medication classes. If a child is receiving >1 medication, the more frequent schedule for laboratory testing is recommended. In formulating the recommendations below, the Voting Panel considered the US Food and Drug Administration (FDA) prescription drug labels (package inserts) in addition to the studies included in the systematic review.

For medications that are known teratogens (e.g., methotrexate, leflunomide), when applicable, pregnancy testing should be considered before usage, and counseling on effective methods of contraception is recommended (17). When required by the

* If the patient is receiving >1 medication, a more restrictive schedule should be used. MTX = methotrexate; SSZ = sulfasalazine; LEF = leflunomide; NSAIDs = nonsteroidal antiinflammatory drugs; HCQ = hydroxychloroquine; TNFi = tumor necrosis factor inhibitor; CBC/diff. = complete blood cell with differential; LFTs = liver function tests.
† Include renal function testing with laboratory studies.
‡ Pregnancy testing should be considered before use, and counseling on use of effective methods of contraception is recommended.
§ Should be rechecked sooner if dosage is increased.

FDA, a Risk Evaluation and Mitigation Strategy should be applied (18).

Baseline laboratory testing is conditionally recommended prior to treatment initiation, for all medications.

Baseline laboratory evaluation is recommended to identify potential contraindications to a specific treatment. This should include complete blood cell count (CBC) with differential cell count and liver function tests (LFTs) (e.g., alanine aminotransferase [ALT] and aspartate aminotransferase), plus renal function tests (e.g., blood urea nitrogen, creatinine, and urinalysis) for patients being treated with methotrexate, sulfasalazine, or nonsteroidal anti-inflammatory drugs (NSAIDs) and lipid profiles for patients being treated with tocilizumab and tofacitinib. Additional laboratory testing may be performed at the discretion of the treating clinician.

NSAIDs (all)

Monitoring via CBC counts, LFTs, and renal function tests every 6–12 months is conditionally recommended.

NSAIDs are known to be associated with gastrointestinal (GI) bleed risk and liver and kidney toxicity in adults with rheumatic diseases. Although these may be rare in children, the Voting Panel deemed it important to monitor for laboratory abnormalities periodically in children receiving long-term NSAIDs. Because GI distress when consistently taking NSAIDs is common, patients/caregivers strongly suggested that clinicians should inquire about and potentially treat GI symptoms, which may not always be spontaneously reported (19,20).

Methotrexate

Monitoring via CBC counts, LFTs, and renal function tests within the first 1–2 months of usage and every 3–4 months thereafter is strongly recommended.

Voting panelists debated whether frequent methotrexate toxicity monitoring (as per the package instructions, i.e., CBC count monthly and renal/liver function every 1–2 months) should be recommended for children, given the low incidence of liver toxicity (21,22). However, rare potential for serious harm in children and consistency in monitoring schedule during pediatric-to-adult care transition influenced the panel's decision to provide a strong recommendation for frequent monitoring (23).

Decreasing the methotrexate dosage or withholding methotrexate is conditionally recommended if a clinically relevant elevation in LFT results or decreased neutrophil or platelet count is found.

The panel did not reach consensus on specific values to define elevated LFT results or reduced cell counts. Clinically

relevant laboratory abnormalities may include repetitive minor abnormalities or a single major abnormality. LFT results may be transiently elevated if testing is done within 2 days after administration of methotrexate; hence, testing within this window is discouraged.

Use of folic/folinic acid in conjunction with methotrexate is strongly recommended.

Use of folic/folinic acid with methotrexate may mitigate adverse events and improve tolerability (24,25).

Sulfasalazine

Monitoring via CBC counts, LFTs, and renal function tests within the first 1–2 months of usage and every 3–4 months thereafter is conditionally recommended.

Recommended monitoring is less frequent than suggested in the package insert for sulfasalazine (which suggests CBC counts and LFTs every second week in the first 3 months, monthly during the next 3 months, and then every 3 months) because most children have fewer comorbidities and polypharmacy usage is rare, allowing for fewer drug interactions (26–28).

Decreasing the sulfasalazine dosage or withholding sulfasalazine is conditionally recommended if a clinically relevant elevation in LFT results or decreased neutrophil or platelet count is found.

While adverse reactions can be serious, including Stevens-Johnson syndrome or drug reaction with eosinophilia and systemic symptoms syndrome (DRESS) (29), the Voting Panel thought the data were too limited to make this recommendation strong.

Leflunomide

Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is conditionally recommended.

Recommended LFT monitoring is less frequent than suggested in the leflunomide package insert (which recommends CBC counts and ALT testing monthly for 6 months and then every 6–8 weeks) (30) because most children have fewer comorbidities and polypharmacy usage is rare, allowing for fewer drug interactions (31).

Altering leflunomide administration is conditionally recommended if a clinically relevant elevation in LFT results occurs (temporary withholding of leflunomide if the ALT level is >3 times the upper limit of normal [ULN]), as per the package insert.

Elimination of leflunomide can be accelerated with the use of cholestyramine or activated charcoal (30), when required.

Hydroxychloroquine

Monitoring via CBC counts and LFTs annually is conditionally recommended.

As per the hydroxychloroquine package insert (32), periodic laboratory monitoring should be performed if patients are receiving prolonged therapy.

Baseline and annual retinal screening after starting hydroxychloroquine are conditionally recommended.

Yearly screening should be performed in pediatric patients, rather than waiting 5 years between baseline and subsequent annual screening as recommended for hydroxychloroquine-treated adults (33). The cumulative and developmental effects of hydroxychloroquine are a concern because children may be receiving treatment for prolonged periods and may not be able to articulate vision concerns. Baseline retinal screening should be completed as soon as possible and combined with screening for uveitis when feasible. Treatment does not need to be delayed for initial retinal screening.

Tumor necrosis factor inhibitors (TNFi) (all)

Monitoring via CBC counts and LFTs annually is conditionally recommended.

As per package inserts, cytopenias and abnormal LFTs have been reported in association with TNFi treatment. Therefore, evaluation yearly at minimum is recommended (34,35).

Abatacept

Doing no routine laboratory monitoring is conditionally recommended.

In placebo-controlled clinical trials of abatacept for JIA, children had similar CBC counts and LFT results irrespective of treatment arm (36), and no laboratory monitoring is suggested in the package insert (37). The decision to perform laboratory monitoring may be discussed with patients/caregivers who, like some of the voting panelists, may prefer routine monitoring to identify potential adverse events, even if rare.

Tocilizumab

Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is conditionally recommended.

Monitoring of lipid levels every 6 months is conditionally recommended, as per the package insert.

Altering tocilizumab administration is conditionally recommended if monitoring reveals elevated LFT results (if 1–3 times the ULN, decrease the dosage or increase the interval between doses, if >3 times the ULN, withhold administration, if >5 times the ULN, discontinue treatment), neutropenia (500–1,000/mm^3), or thrombocytopenia (50,000–100,000/mm^3), as per the package insert.

As per the package insert, initiation of tocilizumab treatment is not recommended in patients with elevated LFT results (>1.5 times the ULN) (38). In patients in whom LFT results become highly elevated (>5 times the ULN), treatment should be discontinued. The package insert does state that the decision to discontinue tocilizumab due to a laboratory abnormality should be based on the medical assessment of the individual patient. For that reason, this recommendation is conditional.

Anakinra

Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is conditionally recommended.

Abnormal LFTs and neutropenia may occur with the use of anakinra (39). For that reason, as well as the severity of the underlying disease, regular monitoring should be performed.

Canakinumab

Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is conditionally recommended.

Abnormal LFT results and cytopenias were noted during a phase III clinical trial of canakinumab for systemic JIA (40). For that reason, as well as the severity of the underlying disease, regular monitoring should be performed.

Tofacitinib

Monitoring via CBC counts and LFTs within the first 1–2 months of usage and every 3–4 months thereafter is conditionally recommended.

Monitoring of lipid levels 1–2 months after starting treatment is conditionally recommended, as per the package insert.

Altering tofacitinib administration is strongly recommended if monitoring reveals laboratory abnormalities of concern. Specifically, medication should be discontinued if the hemoglobin level is <8 gm/dl or decreases by >2 gm/dl, or for severe neutropenia (<500/mm^3) or lymphopenia (<500/mm^3), as per the package insert.

Data on tofacitinib were not part of the initial literature review, but the panel considered it important to include this recommendation because in 2020 tofacitinib was approved by the FDA for treatment of JIA (41). An additional Voting Panel session was organized for this purpose.

Infection surveillance (Table 6)

Tuberculosis (TB)

TB screening is conditionally recommended prior to starting biologic disease-modifying antirheumatic drug (DMARD) therapy and when there is a concern for TB exposure thereafter.

Concern for TB exposure should be interpreted broadly and could include contact with someone with active TB, travel to locations where TB is endemic, contact with high-risk individuals (e.g., prisoners, visitors from TB-endemic areas), or living in communities with a higher frequency of TB (42,43). The conditional recommendation reflects 2 major concerns: In certain urgent clinical situations, the harms of waiting for results of TB screening may outweigh the benefits of treatment. For example, in a child with active systemic JIA and macrophage activation syndrome (MAS), treatment should not be delayed pending TB screening results. Annual screening for TB can pose problems for children and families. Insurers or institutions may require a specific method that is potentially problematic (44,45). For example, TB screening may be done by questionnaire; however, this depends on knowledge of exposure. The interferon-γ release assay is expensive, not valid in young children, and subject to frequent indeterminate results, particularly during anergy. Tuberculin skin testing is user dependent and inconvenient because 2 visits are required. In addition, false-positive results often lead to unnecessary chest radiography and isoniazid treatment. For children living in areas with a low prevalence of TB, mandatory annual laboratory-based TB screening represents a high burden of cost, inconvenience, and pain that is not supported by the literature reviewed.

Viral infections

Voting panelists could not reach consensus on whether all children with JIA should have antibody titers for specific infections (e.g., measles, varicella, hepatitis B, hepatitis C) checked prior to starting immunosuppressive medication, although more panelists were against this practice than for it. Some panelists believed the information might be useful for risk management in case of an outbreak or exposure. Most believed that screening a fully immunized child was of low benefit and might delay treatment and incur unnecessary cost. Although

Table 6. Infection surveillance/immunizations*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
No consensus achieved.	Very low	PICO 45. Should all children with JIA have infection titers (measles, varicella, hepatitis B, hepatitis C) checked prior to starting immunosuppressive medication?	164–166
Immunization is **conditionally** recommended for children with active non-systemic JIA who have not yet been immunized for measles, mumps, rubella, and/or varicella prior to starting immunosuppressive medications.	Very low	PICO 46. Should children with JIA with no evidence of immunity to important infections have a booster immunization prior to starting immunosuppressive medication?	166
TB screening is **conditionally** recommended prior to starting biologic DMARD therapy and when there is a concern for TB exposure thereafter.	Very low	PICO 47. Should screening for TB be done prior to starting biologic DMARD therapy and then annually in children with JIA?	167–169
	Very low	PICO 48. In children with JIA receiving biologic DMARD therapy, is there a preferred method of TB screening?	169–171
Immunizations (live and inactivated) are **strongly** recommended for children with JIA who are not receiving immunosuppressive treatment.	Very low	PICO 49. In children with JIA not receiving immunosuppressive treatment, do inactivated or live attenuated vaccines result in flare of disease?	172–175
Annual inactivated influenza immunization is **strongly** recommended for all children with JIA.	Low	PICO 50. In children with JIA not receiving immunosuppressive treatment, are patients able to develop protective antibodies against infections targeted by the vaccine?	175–179
		PICO 52. In children with JIA receiving immunosuppressive treatment, are patients able to develop protective antibodies against infections targeted by the vaccine?	184–195
Inactivated vaccines are **strongly** recommended for children who are receiving immunosuppressive treatment.	Very low	PICO 51. In children with JIA receiving immunosuppressive treatment, do inactivated vaccines result in flare of disease?	180–184
Live attenuated vaccines are **conditionally** recommended *against* in children with JIA who are receiving immunosuppressive treatment.	Low	PICO 53. In children with JIA receiving immunosuppressive treatment, can treatment with live attenuated vaccines be given safely (initial dose, booster dose)?	195–198
Vaccines are **strongly** recommended for household contacts of children with JIA who are receiving immunosuppressive treatment.	Very low	PICO 54. Can live attenuated vaccines be used safely in the households of children with JIA receiving immunosuppressive treatment?	198

* PICO = Patient/Population, Intervention, Comparison, and Outcomes; JIA = juvenile idiopathic arthritis; TB = tuberculosis; DMARD = disease-modifying antirheumatic drug.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract.

screening for hepatitis B and C is done in adults prior to treatment with DMARDs, most children are effectively immunized against hepatitis B as infants (46), and the number of children below the age of 19 years with hepatitis C in the US remains exceedingly low (47).

Immunizations (Table 6)

Because some patients/caregivers have concerns about the safety of vaccines in JIA, clinicians must discuss with families the evidence that strongly supports their benefits and safety. Whenever possible, immunizations should be administered according to the schedule recommended by the ACIP and the AAP or corresponding national recommendations. As immunization schedules are frequently updated, clinicians should ensure that they are using the most recent versions (48). Multiple cohort studies have demonstrated that most children with JIA mount a protective response after immunizations and that immunizations do not cause disease flare (49–52).

Annual inactivated influenza immunization is strongly recommended for all children with JIA

All children with JIA, including children receiving immunosuppressive medication, should receive inactivated influenza immunizations annually (53). This recommendation is strong despite very low evidence in JIA, given the overwhelming preponderance of supporting literature in other inflammatory diseases and the risk of severe infection (54–57). Intranasal influenza immunization is contraindicated for children with JIA who are receiving immunosuppressive treatment, as it is a live attenuated immunization.

Table 7. Imaging*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
Use of radiography as a screening test prior to advanced imaging, for the purpose of identifying active synovitis or enthesitis, is **strongly** recommended *against*.	Very low	PICO 55. In children with JIA, is any specific imaging technique recommended to best detect inflammation and damage, make a diagnosis, and predict structural damage, flare, or treatment response?	199–268
Imaging guidance is **conditionally** recommended for use with intraarticular glucocorticoid injections of joints that are difficult to access, or to specifically localize the distribution of inflammation.	Very low	PICO 56. In children with JIA who require intraarticular glucocorticoid injections, should injections be done with imaging guidance?	269–279

* PICO = Patient/Population, Intervention, Comparison, and Outcomes; JIA = juvenile idiopathic arthritis.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract.

Immunizations (live attenuated and inactivated) are strongly recommended for children with JIA who are not receiving immunosuppressive treatment

Children with JIA have a higher risk of severe infection compared to unaffected children, making adequate protections against infection essential (58). Considerations of the relative degree of immunosuppression from various immunosuppressive medications used for JIA is beyond the scope of this project. To err on the side of safety, these recommendations apply equally to any child receiving an immunosuppressive medication for JIA (e.g., DMARDs, long-term systemic glucocorticoids) (59).

Inactivated vaccines are strongly recommended for children with JIA who are receiving immunosuppressive treatment.

Persons with JIA should receive inactivated vaccines as per location-specific, published age-related schedule. Specifically, children undergoing immunosuppressive treatment should receive the 23-valent pneumococcal polysaccharide vaccine in addition to the 13-valent pneumococcal conjugate vaccine recommended for all children (60,61).

Live attenuated vaccines are conditionally recommended *against* in children with JIA who are receiving immunosuppressive treatment.

As reported by the US Centers for Disease Control and Prevention (CDC), severe complications have followed vaccination with certain live attenuated viral and bacterial vaccines among immunosuppressed persons (62). Therefore, guidelines recommend that persons with most forms of altered immunocompetence should not receive live attenuated vaccines. According to the CDC, live-virus vaccination should be deferred for 1–6 months after discontinuation of immunosuppressive treatment, depending on the specific agent (62). There is some evidence that booster immunization with live attenuated vaccines may be safe for children with JIA who are receiving certain specific immunosuppressants (52,63). More work is needed to support a formal recommendation in this setting, as studies thus far have been underpowered to detect rare, serious harms.

Immunization is conditionally recommended for children with active non-systemic JIA who have not yet been immunized for measles, mumps, rubella, and/or varicella prior to starting immunosuppressive medications.

This recommendation excludes active, untreated systemic JIA in which delaying treatment initiation for vaccinations may be prohibitive. As per the CDC, immunosuppressive therapy should not be initiated until 4 weeks after administration of a live vaccine and ideally 2 weeks after administration of an inactivated vaccine. If withholding/delaying medication is not feasible, live-attenuated vaccine immunization should be deferred and given at a later time when disease is in remission and the child is no longer being treated (64).

Vaccines are strongly recommended for household contacts of children with JIA who are receiving immunosuppressive treatment.

Immunization of household members of immunosuppressed children is critical to diminish exposure in the home. Household contacts and other close contacts of persons with altered immunocompetence should receive all age- and exposure-appropriate vaccines, whether inactivated or live, with the exception of smallpox vaccine (59,65). If a family member has received varicella vaccine and develops a rash, direct contact should be avoided until the rash resolves. Likewise, all members of the household should wash their hands after changing the diaper of an infant who recently received rotavirus vaccine, to minimize transmission. If concerns remain, CDC or local guidelines can be reviewed prior to immunization.

Imaging (Table 7)

Use of radiography as a screening test prior to advanced imaging, for the purpose of identifying active synovitis or enthesitis, is strongly recommended *against*.

Radiography is not sensitive enough to assess joint inflammation and enthesitis in children and may delay clinically appropriate imaging and treatment (66–68). Unnecessary radiation can result in significant harm to developing children (69). Conventional

radiography should be restricted to the assessment of JIA-associated damage or to investigate alternative diagnoses.

Imaging guidance is conditionally recommended for use with intraarticular glucocorticoid injections of joints that are difficult to access, or to specifically localize the distribution of inflammation.

This recommendation includes ultrasound and/or fluoroscopy. Specific joints that may be difficult to access include sacroiliac joints, hips, TMJs, shoulder, midfoot, and subtalar joints. This recommendation is conditional because it is dependent on the skill of the practitioner, availability of imaging, costs, and risk of delay in treatment (70–72).

DISCUSSION

The recommendations presented in this guideline are a companion to those published in 2019 (3,4) and concurrently (73) and cover areas not previously addressed in JIA: nonpharmacologic treatments, medication monitoring, immunization, and imaging. Similar to recommendations made for oligoarthritis, TMJ arthritis, and systemic JIA with and without MAS, one must view this guideline as a road map for future study (Supplementary Appendix 7, available on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42036/abstract). Most of the available evidence was very low quality for the relevant PICO questions, contributing to 23 of the 33 recommendations being conditional. None of the recommendations were supported by moderate- or high-quality evidence.

Nowhere is the discrepancy between patient/caregiver interest and available data more evident than in the consideration of nonpharmacologic therapies, for which recommendations were included at patient/parent request. Use of specific diets and supplements was discussed extensively by the patient/caregiver panel, including sharing of suggested regimens and reference materials. There was a general belief that disease manifestations could be ameliorated by changes in foods consumed and great interest in participating in formal research studies on nutritional interventions. Most panelists recognized the importance of PT/OT, and inclusion of PT and OT specialists on the Voting Panel would allow for more specific recommendations in future guidelines.

Likewise, patients and caregivers discussed the stress of dealing with chronic illness and the need for mental health interventions. As recently as 2017, when the scope of this project was established, mental health care for children and families affected by rheumatic diseases was not a major focus. For this reason, although mental health was recognized by the Voting Panel as important, it was not formally addressed in this guideline. Future guidelines should include recommendations addressing mental health screening and treatments, with input from mental health professionals on the Voting Panel. This is particularly important given the impact of the COVID-19 pandemic on the mental health of persons with chronic disease (74).

Medication monitoring remains especially challenging in JIA, and balancing safety, cost, pain, and inconvenience can be very difficult. Some panel members asserted that monitoring was perhaps less important in a generally healthy pediatric population relative to adults with comorbidities. Due to the low frequency of serious comorbidities and interacting medications, and limited-to-no exposure to alcohol and other toxins, laboratory abnormalities requiring medication discontinuation are rare in children with JIA. However, other panel members believed strongly that monitoring needs to be routinely performed to identify rare but serious adverse events. Recommendations as written attempted to balance these concerns. Future research and guidelines should consider altered, less frequent monitoring schedules for younger children, given the potentially lower risks of toxicity and greater risks of frequent testing at the youngest ages.

The list of available immunosuppressive medications for JIA for which monitoring is required has grown substantially and will continue to expand. Two new agents were recently approved for use in polyarticular-course JIA: golimumab (a TNFi) and tofacitinib (a JAK inhibitor) (41,75). With regard to laboratory testing to detect abnormalities in monitoring for toxicity, voting panelists could not agree on a single definition of "clinically relevant" abnormal results and left this to the discretion of treating clinicians. Caregivers and patients expressed the challenges of balancing the need to ensure medication safety with the cost and inconvenience associated with blood withdrawal. It is hoped that in the future, effective, reliable treatments that require less monitoring will be available for JIA.

Voting panelists did believe strongly that age must be taken into consideration in requirements for infection screening in the US prior to initiation of treatment with DMARDs. TB, hepatitis B, and hepatitis C are extremely rare in fully immunized nonimmigrant children in the US, and annual TB screening presents a large and unnecessary burden. There were engaged discussions about screening for viral infections prior to the use of DMARDs; however, most thought that lack of immunity in a child known to be immunized was likely to be rare. Even if antibody titers were low or absent after vaccination, cell-mediated immunity was considered likely to be present.

In light of the COVID-19 pandemic, discussion of immunizations in these guidelines proved to be extremely timely. Despite the potential severity of vaccine-preventable infections in immunosuppressed populations, vaccine hesitancy remains common. Nonetheless, preventing infectious illnesses in an immunosuppressed patient population is critical. Many families have concerns regarding vaccine safety, immunogenicity, risk of flare, and other potential long-term consequences. Studies in JIA have consistently demonstrated the safety and effectiveness of vaccines to induce protective immune responses. Regarding immunization for COVID-19, available immunizations vary by

age, accessibility, and country. There are currently no preferences for a specific vaccine in a given population of children with rheumatic disease. Physicians should refer to local recommendations. At the time this manuscript was approved for publication, the Pfizer-BioNTech COVID-19 vaccine was approved in the US for adolescents age ≥16 years (76) and authorized for emergency use in children 5–15 years of age (77,78). No vaccines for COVID-19 were yet available for younger children, although studies are ongoing. As none of the currently available vaccines against COVID-19 are live vaccines, recommendations should be similar to those stated above for inactivated vaccines. While specific guidance on immunizing children with rheumatic diseases against COVID-19 is still lacking, the ACR has published guidance on COVID-19 vaccines for adults with rheumatic and musculoskeletal diseases (79). Patients and family members have articulated the importance of health care providers for reliable medical information. We must be mindful that clinicians are trusted sources of information about this important public health issue and should discuss immunizations with their patients.

With regard to imaging, it is clear that different modalities are appropriate for different indications. Radiographs are not useful for evaluation of soft tissue disease, and continued third-party payor requirements for radiographs prior to any and all magnetic resonance imaging (MRI) are a waste of resources and a potential hazard to persons with JIA. MRI itself may require sedation, and there is concern that repeated sedation in young children may carry risks (80). More research is needed to define and standardize the best approaches to imaging in children with JIA for different diagnostic and disease management decision-making purposes.

Addressing each area of the JIA guidelines at the same time proved to be a Herculean task. This update of the ACR JIA guidelines has taken 4 years to complete, leading to 4 manuscripts; certain areas are already ready for further updates. Health care around the world is quickly changing in unforeseen ways, and rheumatologists have been thrust into the forefront of recent pandemic developments in an unparalleled manner (81). The pace of change will likely only increase, and guidelines will need to be updated nimbly and more frequently over time.

The low quality of evidence supporting most of the recommendations underscores the importance of clinical judgment and shared decision-making in everyday care of patients with JIA. Similarly, these guidelines and the many uncertainties therein represent a powerful reminder of the need for more high-quality evidence to support (or refute) current practices and to improve disease management in—and well-being of—all individuals living with JIA.

In conclusion, this 2021 updated ACR guideline for JIA recommends the use of PT and OT interventions; a healthy, well-balanced, age-appropriate diet; specific laboratory monitoring for different antirheumatic medications; widespread use of immunizations; and need for shared decision-making with patients/caregivers. The JIA guidelines will continue to be updated as new evidence emerges.

ACKNOWLEDGMENTS

We thank Jennifer Horonjeff who (along with author Katherine Murphy) participated in the Patient Panel meeting. We thank the ACR staff, including Regina Parker for assistance in coordinating the administrative aspects of the project and Cindy Force for assistance with manuscript preparation. We thank Janet Waters for assistance in developing the literature search strategy as well as performing the initial literature search and update searches.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Onel had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception and design. Onel, Horton, Lovell, Shenoi, Cuello, Lee, Murphy, Barbar-Smiley, Edelheit, Sullivan, Turner.

Acquisition of data. Onel, Horton, Lovell, Shenoi, Kimura, Lee, Murphy, Nigrovic, Ombrello, Rabinovich, Twilt, Barbar-Smiley, Cooper, Edelheit, Gillispie-Taylor, Hays, Mannion, Peterson, Flanagan, Saad, Sullivan, Szymanski, Trachtman, Reston.

Analysis and interpretation of data. Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the physician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions, and drug formularies or other third-party analyses that cite ACR guidelines should state this. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The ACR is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To provide updated guidelines for pharmacologic management of juvenile idiopathic arthritis (JIA), focusing on treatment of oligoarthritis, temporomandibular joint (TMJ) arthritis, and systemic JIA with and without macrophage activation syndrome. Recommendations regarding tapering and discontinuing treatment in inactive systemic JIA are also provided.

Methods. We developed clinically relevant Patient/Population, Intervention, Comparison, and Outcomes questions. After conducting a systematic literature review, the Grading of Recommendations Assessment, Development and Evaluation approach was used to rate the quality of evidence (high, moderate, low, or very low). A Voting Panel including clinicians and patients/caregivers achieved consensus on the direction (for or against) and strength (strong or conditional) of recommendations.

Results. Similar to those published in 2019, these JIA recommendations are based on clinical phenotypes of JIA, rather than a specific classification schema. This guideline provides recommendations for initial and subsequent treatment of JIA with oligoarthritis, TMJ arthritis, and systemic JIA as well as for tapering and discontinuing treatment in subjects with inactive systemic JIA. Other aspects of disease management, including factors that influence treatment choice and medication tapering, are discussed. Evidence for all recommendations was graded as low or very low in quality. For that reason, more than half of the recommendations are conditional.

Conclusion. This clinical practice guideline complements the 2019 American College of Rheumatology JIA and uveitis guidelines, which addressed polyarthritis, sacroiliitis, enthesitis, and uveitis. It serves as a tool to support clinicians, patients, and caregivers in decision-making. The recommendations take into consideration the severity of both articular and nonarticular manifestations as well as patient quality of life. Although evidence is generally low quality and many recommendations are conditional, the inclusion of caregivers and patients in the decision-making process strengthens the relevance and applicability of the guideline. It is important to remember that these are recommendations. Clinical decisions, as always, should be made by the treating clinician and patient/caregiver.

INTRODUCTION

Reflecting the changing medical landscape, the American College of Rheumatology (ACR) regularly updates clinical practice guidelines and plans to review these annually and update as needed. The process for updating the 2011 and 2013 juvenile idiopathic arthritis (JIA) guidelines (1,2) began in 2017. Important clinical topics for consideration were first identified at a meeting to define the scope of the guidelines. Advances in the treatment of JIA and better understanding of pathogenesis dictated separating this clinical practice guideline into several parts due to the breadth of topics. The first part, addressing polyarthritis, sacroiliitis, enthesitis, and uveitis, was published in 2 articles in 2019 (3,4). The second part, presented here in 2 articles, covers 1) oligoarthritis, temporomandibular joint (TMJ) arthritis, and systemic JIA, and 2) nonpharmacologic treatments, patient monitoring, immunizations, and imaging (5). The methods and literature review described below reflect the unified process used for the second part of these guidelines, including both articles. Recommendations were intended to be complementary to the 2019 guidelines and are grouped based on disease phenotype and severity, not by specific classification criteria, reflecting decision-making in clinical practice.

Following the selection of topics, we developed clinically relevant Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions. Using Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology, recommendations were then developed based on the best available evidence for commonly encountered clinical scenarios. Prior to final voting, input was sought from relevant stakeholders, including a panel of young adults with JIA and caregivers of children with JIA, to consider their values and perspectives in making recommendations. Both the patient/caregiver and guideline Voting Panels stressed the need for individualized treatment while being mindful of available evidence.

METHODS

This guideline followed the ACR guideline development process and ACR policy guiding management of conflicts of interest and disclosures (https://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines), which include GRADE methodology (6,7) and adheres to Appraisal of Guidelines, Research and Evaluation criteria (8). Supplementary Appendix 1 (available on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract)

This article is published simultaneously in *Arthritis Care & Research*.

Submitted for publication July 7, 2021; accepted in revised form November 23, 2021.

includes a detailed description of the methods. Briefly, the Core Leadership Team (KBO, DBH, DJL, SS) drafted clinical PICO questions. PICO questions were revised and finalized based on feedback from the entire guideline development group and the public. The Literature Review Team performed systematic literature reviews for each PICO (for search terms, see Supplementary Appendix 2, https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract), graded the quality of evidence (high, moderate, low, or very low), and produced the evidence report (Supplementary Appendix 3, https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract). It should be noted that GRADE methodology does not distinguish between lack of evidence (i.e., none) and very low–quality evidence. The Core Team defined multiple critical study outcome(s) for PICOs relevant to each JIA phenotype (Supplementary Appendix 4, https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract).

A panel of 15 members, including young adults with JIA and caregivers of children with JIA, met virtually (moderated by the principal investigator [KBO]), reviewed the evidence report, and provided input to the Voting Panel. Two members of this panel were also members of the Voting Panel to ensure that the patient voice was part of the entire process. The Voting Panel reviewed the evidence report and patient/caregiver perspectives and then discussed and voted on recommendation statements. Consensus required ≥70% agreement on both direction (for or against) and strength (strong or conditional) of each recommendation, as per ACR practice. A recommendation could be either in favor of or against the proposed intervention and either strong or conditional. According to GRADE, a recommendation is categorized as strong if the panel is very confident that the benefits of an intervention clearly outweigh the harms (or vice versa); a conditional recommendation denotes uncertainty regarding the balance of benefits and harms, such as when the evidence quality is low or very low, or when the decision is sensitive to individual patient preferences, or when costs are expected to impact the decision. Thus, conditional recommendations refer to decisions in which incorporation of patient preferences is a particularly essential element of decision-making. Examples of each class of pharmacologic intervention addressed in the recommendations are shown in Table 1.

Rosters of the Core Leadership Team, Literature Review Team, and both panels are included in Supplementary Appendix 5 (https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract).

Guiding principles

The development of the recommendations presented herein was guided by the following principles:

1. Consistent with the ACR's 2019 JIA guidelines, these recommendations are for persons already diagnosed as having JIA.
2. Aside from poor prognostic features specified within the recommendations themselves (e.g., specific joints for oligoarthritis, macrophage activation syndrome [MAS]), coexisting extraarticular conditions that would influence disease management, such as uveitis, psoriasis, or inflammatory bowel disease, are not addressed within these guidelines.
3. Recommendations are intended to be used by all clinicians caring for persons with JIA and assume that patients do not have contraindications to the recommended pharmacologic treatments.
4. Longer-term glucocorticoid therapy in childhood is not appropriate because of its effects on bone health and growth. Thus, wherever glucocorticoids are suggested, recommended treatment should be limited to the lowest effective dose for the shortest duration possible.
5. Shared decision-making with families and patients is important when considering treatment options.

RESULTS/RECOMMENDATIONS

The initial literature review included topics addressed in this report and in the second report (9), and identified 4,308 articles in searches for all PICO questions through August 7, 2019. A July 9, 2020 search update identified 367 more references, for a total of 4,675 articles after duplicates and non-English publications were removed. After exclusion of 2,291 titles and abstracts, 2,384 full-text articles were screened. Of these, 1,939 were excluded (Supplementary Appendix 6, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/

Table 1. Classes of interventions

Nonsteroidal antiinflammatory drugs	Any at therapeutic dosing (ibuprofen, naproxen, tolmetin, indomethacin, meloxicam, nabumetone, diclofenac, piroxicam, etodolac, celecoxib)
Conventional synthetic disease-modifying antirheumatic drugs	Methotrexate, sulfasalazine, hydroxychloroquine, leflunomide, calcineurin inhibitors (cyclosporin A, tacrolimus)
Biologic disease-modifying antirheumatic drugs	Tumor necrosis factor inhibitors (adalimumab, etanercept, infliximab, golimumab, certolizumab pegol); other biologic response modifiers (abatacept, tocilizumab, anakinra, canakinumab)
Glucocorticoids	Oral (any); intravenous (any); intraarticular (triamcinolone acetonide, triamcinolone hexacetonide)

Table 2. Strength of recommendations and quality of supporting evidence*

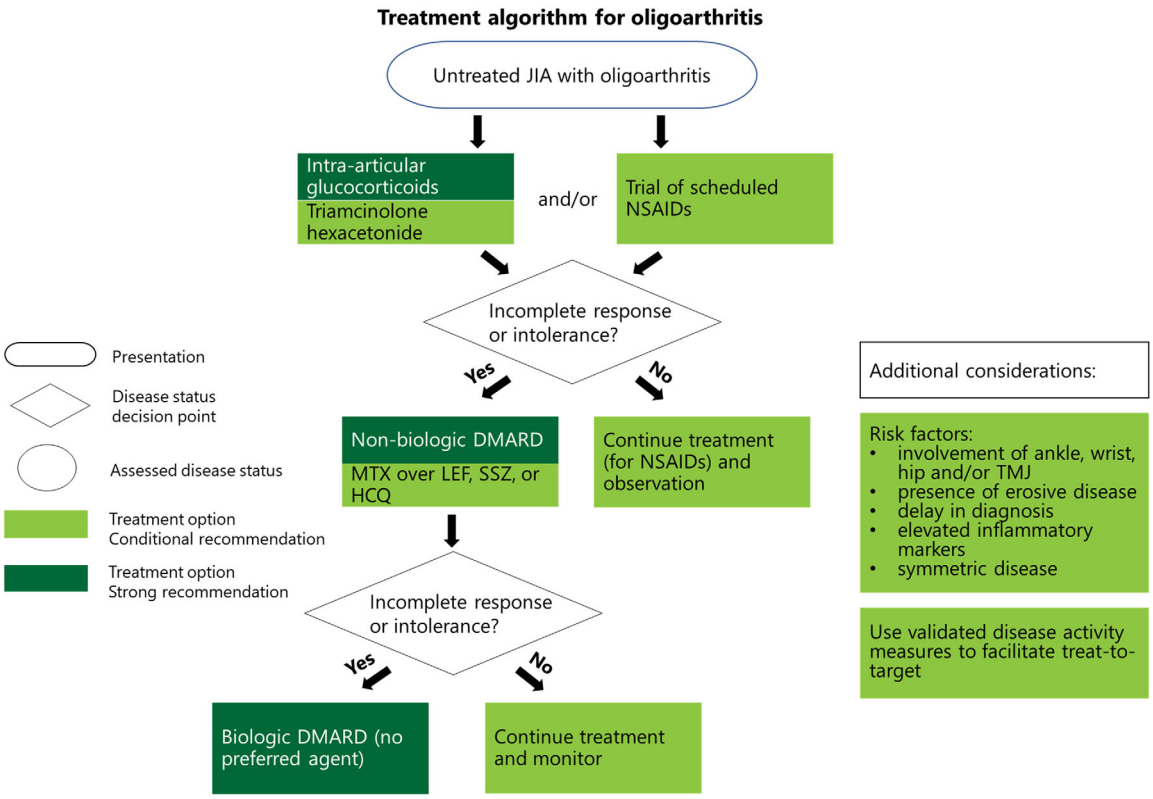
	Strength of recommendation			Quality of supporting evidence			
	No. of recommendations	Conditional	Strong	Very low	Low	Moderate	High
Oligoarthritis	9	5	4	7	2	0	0
TMJ arthritis	7	6	1	7	0	0	0
Systemic JIA	9	5	4	9	0	0	0
Total	25	16	9	23	2	0	0

* TMJ = temporomandibular joint; JIA = juvenile idiopathic arthritis.

art.42037/abstract), leaving 445 articles to be considered for the evidence report. Ultimately, 336 articles were matched to PICO questions and included in the final evidence report. Quality of evidence was uniformly low or very low; 17 PICO questions lacked any associated evidence and as per GRADE methodology were categorized as very low (Tables 2–7). The recommendations that follow are based on 62 PICO questions. Several PICO questions were split into 24 sub-PICO questions to improve specificity. Nine questions initially posed were discarded by the Voting Panel because of redundancy or lack of relevance. Final recommendations are described below and in Tables 3–7, which include reference(s) to which PICO question(s) in the evidence report correspond to the recommendation statement.

Active oligoarthritis (Figure 1 and Table 3)

Oligoarthritis refers to JIA presenting with involvement of ≤4 joints without systemic manifestations. It may include patients with different categories of JIA (10) but who share in common limited numbers of joints involved; guidance for patients with active uveitis, sacroiliitis, or enthesitis can be found in the 2019 guidelines (3,4). TMJ arthritis is discussed separately.



DMARD = disease-modifying antirheumatic drug, HCQ = hydroxychloroquine, JIA = juvenile idiopathic arthritis, LEF = leflunomide, MTX = methotrexate, NSAIDs = nonsteroidal antiinflammatory drugs, SSZ = sulfasalazine, TMJ = temporomandibular joint

Table 3. Oligoarticular JIA*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
A trial of scheduled NSAIDs is **conditionally** recommended as part of initial therapy.	Very low	PICO 1. In children with oligoarticular JIA, should a trial of scheduled NSAIDs be recommended?	6–9
IAGCs are **strongly** recommended as part of initial therapy.	Very low	PICO 2. In children with oligoarticular JIA, should adding IAGCs to initial therapy be recommended?	10–19
Triamcinolone hexacetonide is **strongly** recommended as the preferred agent.	Low	PICO 4. In children with oligoarticular JIA, should a specific steroid type be recommended for intraarticular injection?	21–27
Oral glucocorticoids are **conditionally** recommended *against* as part of initial therapy.	Very low	PICO 3. In children with oligoarticular JIA, should adding oral steroids to initial therapy be recommended?	19–20
Conventional synthetic DMARDs are **strongly** recommended if there is inadequate response to scheduled NSAIDs and/or IAGCs. MTX is **conditionally** recommended as a preferred agent over LEF, SSZ, and HCQ (in that order).	Low (MTX); Very low (LEF, SSZ, HCQ)	PICO 5. In children with oligoarticular JIA, should DMARD therapies be recommended, and should there be any preferred order of treatment: MTX (subcutaneous or oral), LEF, SSZ, and/or HCQ?	28–41
Biologic DMARDs are **strongly** recommended if there is inadequate response to or intolerance of NSAIDs and/or IAGCs and at least 1 conventional synthetic DMARD. There is no preferred biologic DMARD.	Very low	PICO 6. In children with oligoarticular JIA, should biologic therapies be recommended, and should there be any preferred order of treatment: TNFi treatment, biologic treatments with other mechanisms of action?	42–47
Consideration of risk factors for poor outcome (e.g., involvement of ankle, wrist, hip, sacroiliac joint, and/or TMJ, presence of erosive disease or enthesitis, delay in diagnosis, elevated levels of inflammation markers, symmetric disease) is **conditionally** recommended to guide treatment decisions.	Very low	PICO 9. In children with oligoarticular JIA, should poor prognostic features alter the treatment paradigm? PICO 19. In children with JIA with active TMJ arthritis, should poor prognostic features alter the treatment paradigm?	51–52 60
Use of validated disease activity measures is **conditionally** recommended to guide treatment decisions, especially to facilitate treat-to-target approaches.	Very low	PICO 10. In children with oligoarticular JIA, should disease activity measures alter the treatment paradigm?	52

† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract.

Nonsteroidal antiinflammatory drugs (NSAIDs)

A trial of scheduled NSAIDs is conditionally recommended as part of initial therapy for active oligoarthritis.

NSAIDs have long been the cornerstone of treatment for oligoarthritis and can ease discomfort (11–13). However, the initial NSAID trial should be brief due to potential adverse effects (e.g., gastritis, bruising) and limited efficacy (unless inactive disease is achieved). Voting panelists could not agree on the appropriate duration of initial use before escalating therapy, as some panelists prefer that the use of NSAIDs be avoided altogether.

Glucocorticoids

Intraarticular glucocorticoids (IAGCs) are strongly recommended as part of initial therapy for active oligoarthritis.

Triamcinolone hexacetonide is strongly recommended as the preferred agent.

Although the evidence is of low quality, IAGCs are strongly recommended due to low potential of adverse effects and high likelihood of sustained response (14–16). Patients and caregivers agreed with regard to the utility of IAGC but voiced

concerns over the need for sedation in younger children and associated risks.

Despite an overall grading of the evidence as low, the panel was convinced by published randomized trials and large observational studies (17–19) that triamcinolone hexacetonide results in more durable clinical responses than triamcinolone acetonide, leading to the strong recommendation. Triamcinolone hexacetonide has been unavailable in the US for several years. However, very recently, the US Food and Drug Administration (FDA) has allowed the importation of one particular formulation of triamcinolone hexacetonide specifically for joint injections in patients with JIA to address this identified unmet medical need.

Oral glucocorticoids are conditionally recommended *against* as part of initial therapy for active oligoarthritis.

If, despite recommendations against, oral glucocorticoids are given to quickly alleviate severe symptoms when an IAGC is not available or feasible, or prior to the onset of action of disease-modifying antirheumatic drugs (DMARDs), treatment should be limited to the lowest effective dose for the shortest duration possible (20,21).

Conventional synthetic DMARDs (csDMARDs)

Conventional synthetic DMARDs are strongly recommended if there is an inadequate response to scheduled NSAIDs and/or IAGCs for active oligoarthritis.

Methotrexate is conditionally recommended as a preferred agent over leflunomide, sulfasalazine, or hydroxychloroquine (in that order).

Despite an absence of comparator trials, methotrexate is the preferred agent, given the preponderance of evidence showing its long-term safety and efficacy in children (22–24). Because the tolerability of methotrexate is variable, additional treatment options are provided (25–28).

With regard to the route of administration of methotrexate, the 2019 JIA guidelines conditionally recommended subcutaneous over oral administration for polyarthritis (3). This recommendation was conditional because the supporting evidence was of very low quality and patient preferences may guide choice of route of administration. There is little reason to suggest that methotrexate should be used differently in oligoarthritis than in polyarthritis.

Biologic DMARDs (bDMARDs)

Biologic DMARDs are strongly recommended if there is inadequate response to or intolerance of NSAIDs and/or IAGCs and at least 1 csDMARD for active oligoarthritis.

There is no preferred bDMARD.

Biologic DMARDs are preferred over combining csDMARDs or switching to a different csDMARD, due to a greater likelihood that bDMARDs will yield rapid and sustained improvement in JIA (29,30). While combination csDMARDs have been used for the treatment of rheumatoid arthritis in adults, in children the combination appears to be less effective and less tolerable (31). For these reasons, this recommendation is strong.

Although tumor necrosis factor inhibitors (TNFi) are the most commonly used bDMARDs in children (32–34), other bDMARDs of proven efficacy in the treatment of JIA may be used. In the absence of head-to-head trials in children with oligoarthritis (35), bDMARD selection may be driven by specific provider and patient/caregiver preferences and circumstances, with the exception of interleukin-1 (IL-1) inhibitors, which are preferentially used for the treatment of systemic JIA (29,36–38).

Risk factors for poor prognosis and disease activity measures

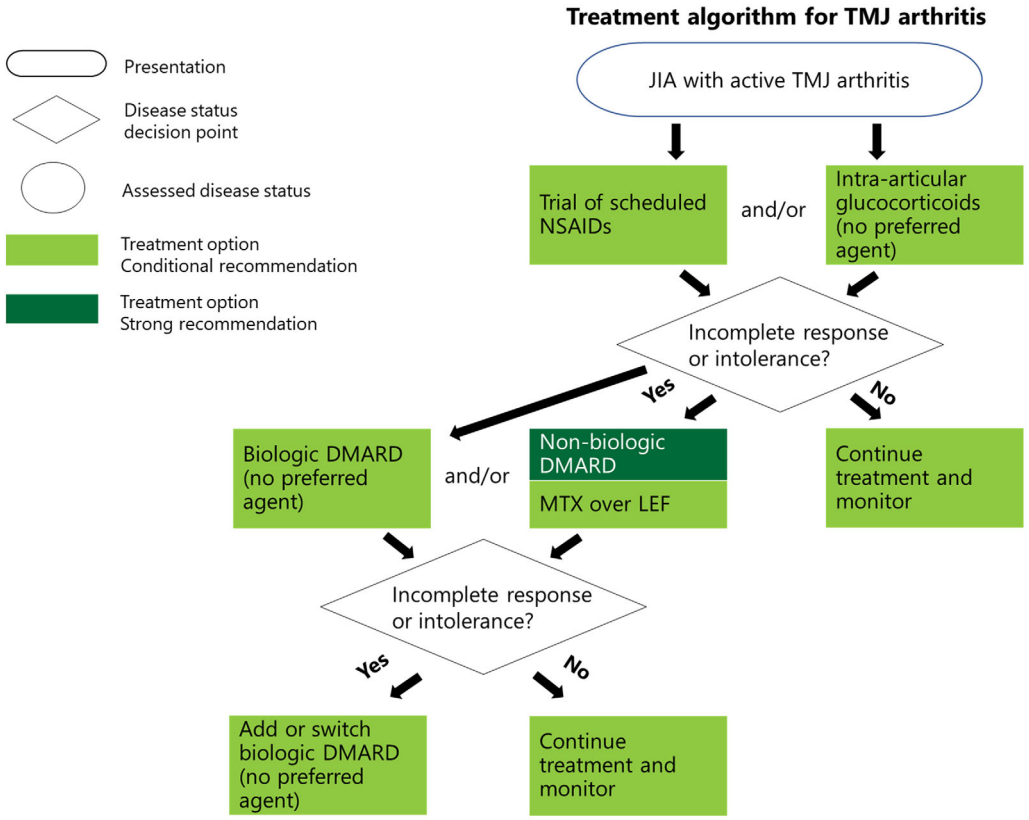
Consideration of risk factors for poor outcome (e.g., involvement of ankle, wrist, hip, sacroiliac joint, and/or TMJ, presence of erosive disease or enthesitis, delay in diagnosis, elevated levels of inflammation markers, symmetric disease) is conditionally recommended to guide treatment decisions.

Use of validated disease activity measures is conditionally recommended to guide treatment decisions, especially to facilitate treat-to-target approaches.

Treatment for oligoarthritis can and should be modified based on the involvement of specific joints or disease features (39,40). This could include rapid escalation of treatment (e.g., if there is TMJ involvement or erosive disease at presentation) or alternative medication choice (e.g., sulfasalazine or bDMARD rather than methotrexate for sacroiliitis) (3).

Voting panelists conditionally recommended formal assessment of disease activity using validated measures. There are several validated disease activity measures for childhood arthritis (41). The lack of demonstrated superiority of specific measures and the likelihood of future changes led voting panelists to defer stating formal preferences for particular measures. Measures that can be considered include Wallace preliminary criteria for Clinical Remission, ACR provisional criteria for inactive disease, Juvenile Arthritis Disease Activity Score (JADAS), and clinical JADAS, among others (42–46).

Treat-to-target approaches have been strongly endorsed for polyarticular JIA (47), and preliminary data have demonstrated feasibility as well as improved outcomes (48,49). Despite the limited number of studies in oligoarticular disease, one would expect a similar response. Presence of risk factors for poor outcomes may justify rapid escalation of treatment.



DMARD = disease-modifying antirheumatic drug, JIA = juvenile idiopathic arthritis, LEF = leflunomide, MTX = methotrexate, NSAIDs = nonsteroidal antiinflammatory drugs, TMJ = temporomandibular joint

Figure 2. Treatment algorithm for temporomandibular joint arthritis.

Active TMJ arthritis (Figure 2 and Table 4)

TMJ disease may be isolated or part of generalized arthritis. Treatment of TMJ arthritis is critical, as patients/caregivers noted high impact on oral health–related quality of life and challenges with diagnosis and effective pharmacologic treatment (50,51). In this guideline, therefore, treatment of TMJ arthritis is recommended regardless of presence of clinical symptoms. While NSAIDs and/or IAGCs may be sufficient treatment for some patients, rapid escalation to bDMARDs (potentially in combination with csDMARDs) is often appropriate despite limited evidence, given the impact and destructive nature of TMJ arthritis (52).

NSAIDs

A trial of scheduled NSAIDs is conditionally recommended as part of initial therapy for active TMJ arthritis.

NSAIDs have long been the cornerstone of treatment for JIA and can ease discomfort (11). However, the initial NSAID trial should be brief due to potential adverse effects (e.g., gastritis, bruising) and limited efficacy (unless inactive disease is achieved). Voting panelists could not agree on the appropriate duration of initial use before escalating therapy, as some panelists prefer that the use of NSAIDs be avoided altogether.

Glucocorticoids

IAGCs are conditionally recommended as part of initial therapy for active TMJ arthritis.

There is no preferred agent.

IAGCs may alleviate joint symptoms and help restore function. This recommendation is conditional, as there have been unique TMJ-specific serious adverse events, including heterotopic ossification and impaired growth (52–55). Therefore, IAGCs for TMJ arthritis should be used sparingly for symptomatic children, preferably those who are skeletally mature (53–56). There are no comparative data between different IAGC formulations for TMJ injections.

Oral glucocorticoids are conditionally recommended *against* as part of initial therapy for active TMJ arthritis.

If, despite recommendations against, oral glucocorticoids are given to quickly alleviate severe symptoms prior to the onset

Table 4. TMJ arthritis*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
A trial of scheduled NSAIDs is **conditionally** recommended as part of initial therapy.	Very low	PICO 11. In children with JIA with active TMJ arthritis, should a trial of scheduled NSAIDs be recommended, and should there be any preferred NSAID treatment?	53
IAGCs are **conditionally** recommended as part of initial therapy.	Very low	PICO 12. In children with JIA with active TMJ arthritis, should adding intraarticular glucocorticoids to initial therapy be recommended?	53–57
There is no preferred agent.	Very low	PICO 14. In children with JIA with active TMJ arthritis, should a specific steroid type be recommended for intraarticular injection?	58
Oral glucocorticoids are **conditionally** recommended *against* as part of initial therapy.	Very low	PICO 13. In children with JIA with active TMJ arthritis, should adding oral glucocorticoids to initial therapy be recommended?	58
Conventional synthetic DMARDs are **strongly** recommended for inadequate response to or intolerance of NSAIDs and/or IAGCs. MTX is **conditionally** recommended as a preferred agent over LEF.	Very low	PICO 15. In children with JIA with active TMJ arthritis, should DMARD therapies be recommended, and should there be any preferred order of treatment: MTX (subcutaneous and oral), LEF, SSZ, and/or HCQ?	58–59
Biologic DMARDs are **conditionally** recommended for inadequate response to or intolerance of NSAIDs and/or IAGCs and at least 1 conventional synthetic DMARD. There is no preferred biologic agent.	Very low	PICO 16. In children with JIA with active TMJ arthritis, should systemic biologic therapies be recommended, and should there be any preferred order of treatment: TNFi, biologic treatments with other mechanisms of action?	59
Consideration of poor prognostic features (e.g., involvement of ankle, wrist, hip, sacroiliac joint, and/or TMJ, presence of erosive disease or enthesitis, delay in diagnosis, elevated levels of inflammation markers, symmetric disease) is **conditionally** recommended to guide treatment decisions.	Very low	PICO 19. In children with JIA with active TMJ arthritis, should poor prognostic features alter the treatment paradigm?	60

* TMJ = temporomandibular joint; PICO = Patient/Population, Intervention, Comparison, and Outcomes; NSAIDs = nonsteroidal antiinflammatory drugs; JIA = juvenile idiopathic arthritis; IAGCs = intraarticular glucocorticoids; DMARDs = disease-modifying antirheumatic drugs; MTX = methotrexate; LEF = leflunomide; SSZ = sulfasalazine; HCQ = hydroxychloroquine; TNFi = tumor necrosis factor inhibitor.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract.

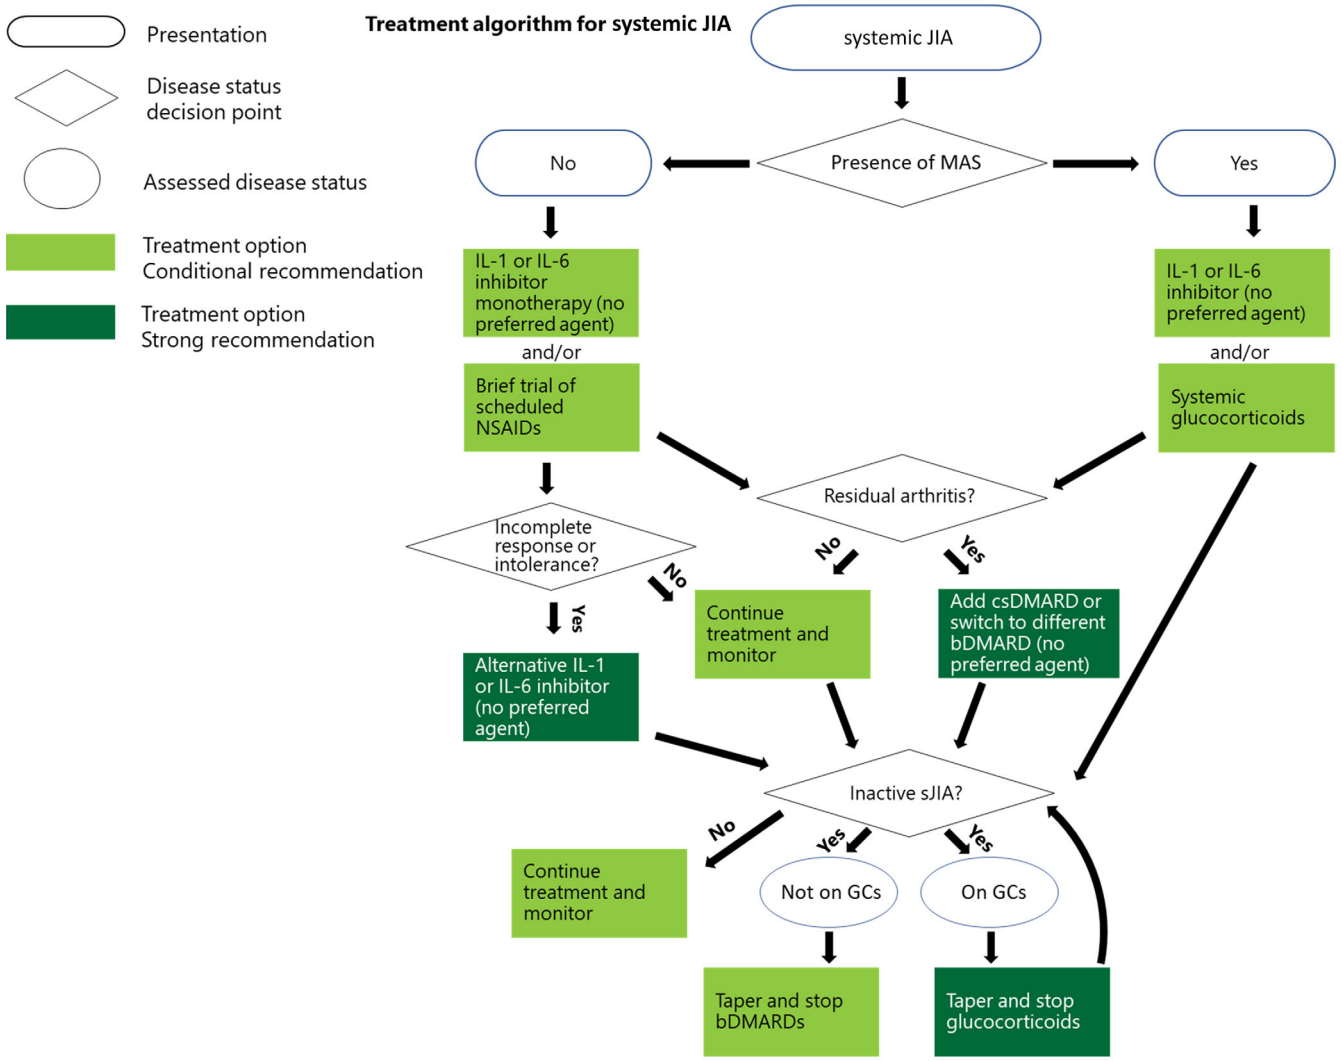
of action of DMARDs, treatment should be limited to the lowest effective dose for the shortest duration possible (20).

Conventional synthetic DMARDs

Conventional synthetic DMARDs are strongly recommended for inadequate response to or intolerance of NSAIDs and/or IAGCs for active TMJ arthritis.

Methotrexate is conditionally recommended as a preferred agent over leflunomide.

The TMJ is a high-risk joint due to major impact on activities of daily living, and thus, early use of csDMARD therapy is encouraged. The limited available evidence supports the use of methotrexate (57). However, because not all patients tolerate methotrexate well, leflunomide is recommended as an alternative, if needed.



bDMARD = biologic disease-modifying antirheumatic drug, csDMARD = conventional synthetic disease-modifying antirheumatic drug, GCs = glucocorticoids, IL = interleukin, JIA = juvenile idiopathic arthritis, MAS = macrophage activation syndrome, NSAIDs = nonsteroidal antiinflammatory drugs

Figure 3. Treatment algorithm for systemic juvenile idiopathic arthritis.

Biologic DMARDs

Biologic DMARDs are conditionally recommended for inadequate response to or intolerance of NSAIDs and/or IAGCs and at least 1 csDMARD for active TMJ arthritis.

There is no preferred bDMARD.

Voting panelists deferred recommending a specific bDMARD because current studies of TMJ arthritis have been small and observational (52,58). TNFi treatment has been most commonly used. As noted above, the use of IL-1 inhibitors is restricted to the treatment of systemic JIA.

Systemic JIA with and without MAS (Figure 3)

Systemic JIA is distinct from all other categories of JIA due to fever, rash, and visceral involvement and is considered by some to be an autoinflammatory disorder (59). Disease pathogenesis and cytokine involvement in systemic JIA are different than in other JIA categories (60–62). Up to 40% of cases of systemic JIA are associated with MAS, a secondary hemophagocytic syndrome that is a life-threatening complication requiring urgent recognition and treatment. MAS presents with fevers, high ferritin levels, cytopenias, elevated liver enzyme levels, low fibrinogen levels, and high triglyceride levels (63,64). As it may occur at any point during the disease course, careful monitoring is necessary for children with or without MAS at presentation.

Systemic JIA without MAS: initial therapy (Table 5)

Biologic DMARDs

Biologic DMARDS (IL-1 and IL-6 inhibitors) are conditionally recommended as initial monotherapy for systemic JIA without MAS.

Table 5. Systemic JIA without MAS*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
NSAIDs are **conditionally** recommended as initial monotherapy. Oral glucocorticoids are **conditionally** recommended *against* as initial monotherapy.	Very low	PICO 20. In patients with treatment-naive, newly diagnosed systemic JIA without MAS, should non-DMARD treatment (NSAIDs, glucocorticoids) be used as initial therapy?	61–67
Conventional synthetic DMARDs are **strongly** recommended *against* as initial monotherapy.	Very low	PICO 21. In patients with treatment-naive, newly diagnosed systemic JIA without MAS, should DMARD treatment (MTX, calcineurin inhibitor) be used as initial therapy, and is there a preferred order?	67–68
Biologic DMARDs (IL-1 and IL-6 inhibitors) are **conditionally** recommended as initial monotherapy. There is no preferred agent.	Very low	PICO 22. In patients with treatment-naive, newly diagnosed systemic JIA without MAS, should biologic treatment (anakinra, canakinumab, tocilizumab, or others) be used as initial therapy, and is there a preferred order?	69–71
IL-1 and IL-6 inhibitors are **strongly** recommended over a single or combination of conventional synthetic DMARDs for inadequate response to or intolerance of NSAIDs and/or glucocorticoids.	Very low	PICO 23. In patients with systemic JIA without MAS who do not respond to initial therapy with nonbiologic treatments (NSAIDs, glucocorticoids, DMARDs), should nonbiologic treatments be combined or biologic treatment started?	72–130
Biologic DMARDs or conventional synthetic DMARDs are strongly recommended over long-term glucocorticoids for residual arthritis and incomplete response to IL-1 and/or IL-6 inhibitors. There is no preferred agent.	Very low	PICO 27. In patients with systemic JIA in whom inactive disease is not achieved despite treatment with both IL-1 and IL-6 agents and/or who are chronically steroid dependent, is long-term stable steroid treatment superior to nonsteroid treatments (cyclophosphamide or abatacept or rituximab or IVIG or mesenchymal stem cell transplant or bone marrow transplant) for achievement of inactive disease, achievement of partial response, growth, ability to taper/discontinue steroids, and minimization of side effects/medication toxicity?	138

* JIA = juvenile idiopathic arthritis; MAS = macrophage activation syndrome; PICO = Patient/Population, Intervention, Comparison, and Outcomes; NSAIDs = nonsteroidal antiinflammatory drugs; DMARD = disease-modifying antirheumatic drug; MTX = methotrexate; IL-1 = interleukin-1; IVIG = intravenous immunoglobulin.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract.

There is no preferred agent.

IL-1 and IL-6 inhibitors are extremely effective and well-tolerated treatments for systemic JIA (60–62) and have been rapidly adopted in clinical practice (65,66). Use of IL-1 and IL-6 inhibitors to treat systemic JIA has allowed for marked reduction in glucocorticoid use (60,61,67). Patients/caregivers agreed with this recommendation, given historical delays and limits in clinical response and toxicities from other medications before the bDMARD era.

Some voting panelists preferred starting with a short-acting agent such as anakinra, but in the absence of controlled studies, no preferred agent was endorsed. Patients/caregivers noted preference for fewer injections, if possible. As response to individual agents is variable, switching among and between IL-1 and IL-6 inhibitors when needed due to lack of efficacy or poor tolerability is appropriate.

Concerns were expressed regarding a highly fatal lung disease observed in some children with systemic JIA, most of whom were treated with bDMARDs. Observed risk factors include younger age with MAS, a history of reactions to tocilizumab, and trisomy 21 (68,69). The exact etiology of systemic JIA–associated lung disease and recommendations for screening remain under

Table 6. Systemic JIA with MAS*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
Formal recommendation deferred	Very low	PICO 24. In patients with systemic JIA, does the presence of subclinical MAS alter the treatment paradigm?	130
IL-1 and IL-6 inhibitors are **conditionally** recommended over calcineurin inhibitors alone to achieve inactive disease and resolution of MAS. Glucocorticoids are **conditionally** recommended as part of initial treatment of systemic JIA with MAS. There is no preferred agent.	Very low	PICO 25. In patients with systemic JIA and overt MAS, is biologic therapy superior to calcineurin inhibitors for achievement of inactive disease and resolution of MAS?	131–136
Formal recommendation deferred	Very low	PICO 26. For nonresponse or partial response to biologic therapy, is addition of a calcineurin inhibitor superior to etoposide or IVIG or plasmapheresis for achievement of inactive disease and resolution of MAS?	137–138
Biologic DMARDs or conventional synthetic DMARDs are **strongly** recommended over long-term glucocorticoids for residual arthritis and incomplete response to IL-1 and/or IL-6 inhibitors. There is no preferred agent.	Very low	PICO 27. In patients with systemic JIA in whom inactive disease is not achieved despite treatment with both IL-1 and IL-6 agents and/or who are chronically steroid dependent, is long-term stable steroid treatment superior to nonsteroid treatments (cyclophosphamide or abatacept or rituximab or IVIG or mesenchymal stem cell transplant or bone marrow transplant) for achievement of inactive disease, achievement of partial response, growth, ability to taper/discontinue steroids, and minimization of side effects/medication toxicity?	138

* JIA = juvenile idiopathic arthritis; MAS = macrophage activation syndrome; PICO = Patient/Population, Intervention, Comparison, and Outcomes; IL-1 = interleukin-1; IVIG = intravenous immunoglobulin; DMARDs = disease-modifying antirheumatic drugs.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract.

investigation. Affected children often present with acute digital clubbing, which should raise immediate concern (68,69). However, voting panelists noted the need to balance the effectiveness and relative safety of bDMARDs with the rarity of this serious outcome. Voting panelists were also motivated by the extent of morbidity from undertreated systemic JIA and glucocorticoid-associated toxicities before the bDMARD era (70,71).

NSAIDs

NSAIDs are conditionally recommended as initial monotherapy for systemic JIA without MAS.

Studies suggest that a small proportion of patients with systemic JIA will respond to NSAIDs alone (72). Patients/caregivers agreed with a short trial of NSAIDs for those children. If clinical response is not rapid and complete, rapid escalation of therapy is recommended. Voting panelists could not agree on the appropriate duration of initial use before escalating therapy, as many panelists prefer that the use of NSAIDs be avoided altogether for systemic JIA.

Glucocorticoids

Oral glucocorticoids are conditionally recommended *against* as initial monotherapy for systemic JIA without MAS.

In most cases, oral glucocorticoids should not be used as initial monotherapy in patients with systemic JIA without MAS and, if used, should be limited to the lowest effective dosage for the shortest duration possible. This recommendation is conditional, as bDMARDs may not always be immediately available, and glucocorticoids may help control systemic and joint manifestations until IL-1 or IL-6 inhibitors can be started.

Table 7. Systemic JIA with inactive disease*

Recommendation	Certainty of evidence	PICO evidence report(s) basis	Page no(s). of evidence tables†
Tapering and discontinuing glucocorticoids is **strongly** recommended after inactive disease has been attained.	Very low	PICO 28. In patients with systemic JIA with inactive disease treated with oral steroids, is taper to discontinuation of steroids superior to continuing long-term stable-dose steroids for preventing disease flare and minimizing side effects/medication toxicity?	139
Tapering and discontinuing biologic DMARDs is **conditionally** recommended after inactive disease has been attained.	Very low	PICO 29. In patients with systemic JIA in clinical remission with biologic monotherapy, is tapering by decreasing dosage superior to tapering dosing interval at preventing disease exacerbation, preventing development of antidrug antibodies, and minimizing medication toxicity?	140–143

* JIA = juvenile idiopathic arthritis; PICO = Patient/Population, Intervention, Comparison, and Outcomes; DMARDs = disease-modifying antirheumatic drugs.
† In Supplementary Appendix 3, on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/10.1002/art.42037/abstract.

Conventional synthetic DMARDs

Conventional synthetic DMARDs are strongly recommended *against* as initial monotherapy for systemic JIA without MAS.

This recommendation is strong despite limited evidence, as the Voting Panel noted multiple small studies of systemic JIA that documented lack of efficacy at controlling systemic features that are typically present at onset of disease, leading to a continued need for glucocorticoids (66,73). Conventional synthetic DMARDs in combination with bDMARDs can be considered for children with prominent arthritis (74). In areas where biologic therapy is not rapidly attainable, thalidomide has been used to treat systemic JIA (75). However, given ready bDMARD availability in North America and risks of thalidomide toxicity, use of thalidomide was not considered as part of this guideline.

Systemic JIA without MAS: subsequent therapy (Table 5)

IL-1 and IL-6 inhibitors are strongly recommended over a single or combination of csDMARDs for inadequate response to or intolerance of NSAIDs and/or glucocorticoids for systemic JIA without MAS.

Most physicians and patients/caregivers preferred quickly starting IL-1 or IL-6 inhibitors for insufficient response to NSAIDs or glucocorticoids (66). Panel members were persuaded by trials that documented resolution of systemic signs and ability to discontinue glucocorticoids (60,76–78).

Biologic DMARDs or conventional synthetic DMARDs are strongly recommended over long-term glucocorticoids for residual arthritis and incomplete response to IL-1 and/or IL-6 inhibitors.

There is no preferred agent.

Given the potential toxicities from long-term use of glucocorticoids (20), patients should receive steroid-sparing treatments for residual arthritis. There are many options (e.g., adding methotrexate, switching to abatacept or a TNFi), and ample evidence supports the use of DMARDs for systemic JIA–associated synovitis (23,79).

Systemic JIA with MAS: initial therapy (Table 6)

Infections can trigger MAS; therefore, all persons with MAS should be evaluated for infection concurrently with or prior to initiation of therapy (80,81).

Biologic DMARDs

IL-1 or IL-6 inhibitors are conditionally recommended over calcineurin inhibitors alone to achieve inactive disease and resolution of MAS for systemic JIA with MAS.

There is no preferred agent.

IL-1 and IL-6 inhibitors have proven to be very helpful in the treatment of systemic JIA and MAS (82–84). Some voting panelists noted that monotherapy may not be sufficient for severely ill patients (83). Biologic DMARDs combined with glucocorticoids and calcineurin inhibitors may be necessary to control MAS in some patients (85).

Glucocorticoids

Glucocorticoids are conditionally recommended as part of initial treatment of systemic JIA with MAS.

The benefits of glucocorticoids for MAS often outweigh their risks, even in patients whose MAS is triggered by infection. Systemic glucocorticoids may be necessary for severely ill patients

because they can have a rapid onset of action. However, although treatment with high-dose glucocorticoids may be required for disease control, subsequent glucocorticoid therapy should be limited to the lowest effective dosage for the shortest duration possible. Longer-term glucocorticoid therapy in children is not appropriate because of its effects on bone health and growth (20).

Systemic JIA with MAS: subsequent therapy (Table 6)

Biologic DMARDS or csDMARDs are strongly recommended over long-term glucocorticoids for residual arthritis and incomplete response to IL-1 and/or IL-6 inhibitors.

Inactive systemic JIA with or without history of MAS (Table 7)

Tapering and discontinuing glucocorticoids is strongly recommended after inactive disease has been attained in systemic JIA.

The risk of flare from systemic JIA that is well controlled is considerably outweighed by possible harms from long-term glucocorticoid use, even at low doses (86), accounting for this strong recommendation. If a patient is receiving both DMARDs and glucocorticoids, systemic glucocorticoids should be tapered and discontinued first before attempting to taper bDMARDs or csDMARDs. It is unclear how soon or rapidly these can be safely discontinued in patients with inactive systemic JIA.

Tapering and discontinuing bDMARDs is conditionally recommended after inactive disease has been attained in systemic JIA.

In children with systemic JIA whose disease is inactive, it may be possible to maintain this inactive disease state with lower doses of, or discontinuation of, bDMARDs (74,87). It is unclear how soon after achievement of inactive disease these can be tapered. No method of tapering is specified (e.g., decreasing dosage versus increasing intervals between doses) given lack of evidence (86), but patients/caregivers tended to prefer increasing intervals.

DISCUSSION

The recommendations presented herein are a companion to those published in 2019 (3,4) and cover areas not previously addressed: oligoarthritis, TMJ arthritis, and systemic JIA with and without MAS. In many ways, one must view this guideline as a road map for future study. Most of the available evidence for the relevant PICO questions was of very low quality, contributing to 16 of the 25 recommendations being conditional. None of the recommendations were supported by moderate- or high-quality evidence. Similar to the 2019 guidelines, recommendations are grouped based on disease phenotype and not by specific classification criteria, reflecting clinical practice, in which disease characteristics, severity, and risk of damage generally drive treatment decisions. These recommendations differ quite substantially from those published in 2011 and 2013 (1,2), reflecting increased experience with and availability of bDMARDs as well as a deeper understanding of JIA pathogenesis and long-term risks of undertreatment.

The Voting Panel and Patient/Caregiver Panel both engaged in vigorous discussions over the use of NSAIDs and oral glucocorticoids (88) in the treatment of JIA, regardless of phenotype. Given the availability of safer, effective alternatives, both panels agreed that these medications should be used sparingly and largely as a bridge until more definitive treatment is available. This is a marked change from previous clinical practice, in which both were mainstays of treatment and subsequent risk of chronic disability was high (89,90).

Another major change in recommendations for the treatment of systemic JIA is the use of bDMARDs as initial treatment or upon inadequate response to a short course of NSAIDs. The addition of csDMARDs is recommended only for persistent synovitis despite treatment with bDMARDs. This recommendation reflects growing understanding about the roles of specific cytokines in systemic JIA and the ability to induce remission with targeted therapy against IL-6 and IL-1 (62,74,91). Reports of a highly fatal lung disease in some bDMARD-treated young children with systemic JIA (68,69) temper this enthusiasm, and additional investigation is needed to determine what role, if any, bDMARDs play in the pathogenesis of this complication.

This guideline's focus on oligoarthritis complements previously published recommendations for polyarthritis (3). However, it was clear in Voting Panel discussions that the number of involved joints alone was insufficient to tailor treatment decisions. Specific involvement of key joints (e.g., TMJ, wrist, sacroiliac, hip, and ankle) and other features (e.g., erosions) were considered reasonable justification for early escalation of therapy (92). This approach is reflected in a distinct set of recommendations specifically addressing TMJ arthritis.

The use of IAGCs was extensively discussed. Recommendations from 2011 and 2019 to preferentially use triamcinolone hexacetonide for oligoarthritis (1,3) were reaffirmed, while no specific formulation for TMJ IAGC injection was noted. Triamcinolone hexacetonide has been shown to be superior to alternative injectable glucocorticoids in achieving and maintaining remission in children with JIA (17–19). Triamcinolone hexacetonide has been commercially unavailable in the US for many years, forcing physicians to consider less effective, more toxic, or more costly alternatives. However, very recently the FDA allowed the importation of one particular formulation of triamcinolone hexacetonide specifically for joint injections in patients with JIA (93) to address an identified unmet medical need.

There is much that remains to be learned. Studies must be performed to obtain high-quality data to fill in the evidentiary gaps (Supplementary Appendix 7, available on the *Arthritis & Rheumatology* website at https://onlinelibrary.wiley.com/doi/

10.1002/art.42037/abstract). There remain important areas with little or no evidence to guide management, suggesting an agenda for future research. Head-to-head trials are needed to understand the optimal order and roles of csDMARDs and bDMARDs for children with JIA. We need improved understanding of which class of medication is best for a particular child, allowing for more precise treatment and less time before remission is attained. Biosimilars were not addressed in this guideline, as these medications were not included in the literature review, and there was no available evidence assessing their use in JIA. More widespread use of biosimilars will add more questions about their relative safety and effectiveness in children who start or switch to them for JIA treatment.

Patient/caregiver input was instrumental in creating these recommendations. Several major themes emerged from their participation. Patients/caregivers stressed the need for individualizing treatments because what works for one does not work for all (94). To facilitate individualization, no rigid time frames were required for an advancement of treatment. Moving quickly may be needed for a patient whose condition is rapidly worsening, while moving more slowly may be appropriate for one whose condition has improved substantially but not fully. Panel participants emphasized the critical importance of shared decision-making that considers patients' and caregivers' values, goals, and preferences (95). The depth and breadth of the impact of JIA on the lives and well-being of affected children and their families cannot be overstated (96,97). It is hoped that in the future, more effective, reliable treatments for this disease will be available (98).

This guideline breaks new ground in recommending treatment withdrawal for children with systemic JIA, who may have lower risks of flare than are associated with other forms of JIA (99,100). As we look toward the future, we can only hope that similar recommendations around tapering medications can be made for every JIA category. There is a need for biomarkers that can help distinguish disease that still requires treatment from that which has completely resolved, as currently the risk of relapse remains high upon medication tapering.

The low quality of evidence supporting these recommendations underscores the importance of clinical judgment and shared decision-making in everyday care of individuals with JIA. Similarly, this guideline and the many uncertainties acknowledged herein represent a powerful reminder of the need for more high-quality evidence to support (or refute) current practices and to improve the management of JIA and well-being of all individuals living with the disease.

ACKNOWLEDGMENTS

We thank Jennifer Horonjeff who (along with author Katherine Murphy) participated in the Patient Panel meeting. We thank the ACR staff, including Regina Parker for assistance in coordinating the administrative aspects of the project and Cindy Force for assistance with manuscript preparation. We thank Janet Waters for assistance in developing the literature search strategy as well as performing the initial literature search and update searches.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Onel had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Swart,[4] Irina Nikishina,[5] Pekka Lahdenne,[6] Lidia Rutkowska-Sak,[7] Tadej Avcin,[8] Pierre Quartier,[9] Violeta Panaviene,[10] Yosef Uziel,[11] Chris Pruunsild,[12] Veronika Vargova,[13] Soamarat Vilaiyuk,[14] Pavla Dolezalova,[15] Sarah Ringold,[16] Marco Garrone,[3] Nicolino Ruperto,[3] Angelo Ravelli,[17] and Alessandro Consolaro,[18] for the Paediatric Rheumatology International Trials Organisation

This work has been approved by the American College of Rheumatology (ACR) Board of Directors. This signifies that it has been quantitatively validated using patient data, and it has undergone validation based on an independent data set. All ACR-approved criteria sets are expected to undergo intermittent updates. The ACR is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To develop and validate new Juvenile Arthritis Disease Activity Score 10 (JADAS10) and clinical JADAS10 (cJADAS10) cutoffs to separate the states of inactive disease (ID), minimal disease activity (MiDA), moderate disease activity (MoDA), and high disease activity (HDA) in children with oligoarthritis and with rheumatoid factor–negative polyarthritis, based on subjective disease assessment by the treating pediatric rheumatologist.

Submitted for publication January 26, 2021; accepted in revised form May 18, 2021.

Methods. The cutoffs definition cohort was composed of 1,936 patients included in the multinational Epidemiology, Treatment and Outcome of Childhood Arthritis (EPOCA) study. Using the subjective physician rating as an external criterion, 4 methods were applied to identify the cutoffs: mapping, Youden index, 90% specificity, and maximum agreement. The validation cohort included 4,014 EPOCA patients, patients from 2 randomized trials, and 88 patients from the PharmaChild registry. Cutoff validation was conducted by assessing discriminative and predictive ability.

Results. The JADAS10 cutoffs were 1.4, 4, and 13, respectively, for oligoarthritis and 2.7, 6, and 17, respectively, for polyarthritis. The cJADAS10 cutoffs were 1.1, 4, and 12, respectively, for oligoarthritis and 2.5, 5, and 16, respectively, for polyarthritis. The cutoffs discriminated strongly among different levels of pain and morning stiffness, between patients who were and those who were not prescribed a new medication, and between different levels of improvement in clinical trials. Achievement of ID and MiDA according to the new JADAS cutoffs at least twice in the first year of disease predicted better outcome at 2 years.

Conclusion. The 2021 JADAS and cJADAS cutoffs revealed good metrologic properties in both definition and validation samples, and are therefore suitable for use in clinical trials and routine practice.

INTRODUCTION

Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease with a widely variable clinical course and outcome (1). Persistently active disease and uncontrolled synovial inflammation may cause structural joint damage (2), which may in turn lead to serious impairment of physical function and have marked impact on the quality of life of children and their families (3,4). Thus, regular assessment of the level of disease activity in children with JIA is fundamental to monitor the course of the disease over time and the effectiveness of therapeutic interventions. A precise measurement of disease activity may also have prognostic implications. For instance, achievement of the state of inactive disease (ID) at least once in the first 5 years was found to be associated with lower levels of long-term damage and functional impairment (5). Furthermore, the time spent in the state of active disease in the first 2 years was the most significant factor associated with the duration of active disease over the following years (6).

In the last decade, the use of composite disease activity scores in JIA has gained increasing popularity. These tools enable an easy and pragmatic approach to the quantification of disease activity by providing a summary number on a continuous scale, which is calculated by calculating the simple arithmetic sum of the scores of their individual components. The first composite disease activity score for JIA was developed in 2009 and was named the Juvenile Arthritis Disease Activity Score (JADAS) (7). The JADAS includes the following 4 measures: physician global assessment of disease activity measured on a 0–10 visual analog scale (VAS), parent/patient global assessment of child well-being measured on a 0–10 VAS, count of joints with active disease among the total assessed (10, 27, or 71 joints depending on the version), and the erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) level (8), both normalized to a 0–10 scale. A simplified, 3-item version of the score called the clinical JADAS (cJADAS), which excludes the acute-phase reactants, was subsequently published (9). Among the different versions of the score, the JADAS10 and the cJADAS10 have been more widely adopted as they are simpler than and equally effective as the other versions.

Proper interpretation of the scores obtained with JADAS calculation requires the definition of criteria for identifying high and low levels of disease activity (10). Cutoff values to separate the states of ID, minimal disease activity (MiDA), moderate disease activity (MoDA), and high disease activity (HDA) were established for both the JADAS (11,12) and the cJADAS (13). These cutoffs were defined with reference to published criteria for clinically inactive disease (CID) (14) and MiDA (15). At the time of previous cutoff definition, these criteria were considered as the only available external reference. However, use of these criteria has some limitations. The published criteria for CID include 3 of the 4 items in the JADAS, all of which must be scored zero. Thus, the variability of the JADAS in a patient who meets the criteria for CID can only be due to the fourth component, i.e., the parent/patient global assessment of the child's well-being. Similar concerns could be raised with regard to the definition of MiDA and the related JADAS cutoffs. Previous cutoffs for HDA were based on the treatment choices made by the treating physician. Potential limitations of the latter approach are that therapeutic choices may be driven by factors other than disease activity and that therapeutic decisions may vary across pediatric rheumatologists practicing in diverse geographic settings or with different clinical experience.

In a recently completed project (16), a large multinational cohort of JIA patients was enrolled and data collected on the treating physician's subjective rating of disease activity. In the present study, we took advantage of this large data set to develop and test new JADAS10 and cJADAS10 cutoffs for oligoarthritis and rheumatoid factor (RF)–negative polyarthritis disease activity states based on the subjective perception of international pediatric rheumatologists.

PATIENTS AND METHODS

Patient population used for the development of JADAS cutoffs. The cutoff definition cohort was selected from among the consecutive JIA patients included in the multinational Epidemiology, Treatment and Outcome of Childhood Arthritis (EPOCA) study (16), whose aims were to investigate the prevalence of JIA categories in different geographic areas, to gain

information on the treatments prescribed by international pediatric rheumatologists, and to assess the disease and health status of children with JIA living in diverse parts of the world. The EPOCA study included 9,081 patients enrolled in 49 countries between April 4, 2011 and November 21, 2016. For the purpose of the study, each JIA patient underwent a cross-sectional visit, during which the treating physician was asked to subjectively rate the disease status as ID, MiDA, MoDA, or HDA.

The oligoarthritis cutoff definition cohort consisted of the patients enrolled at the 20 centers that provided the largest sample of patients with persistent oligoarthritis. The number of oligoarthritis patients in each center ranged from 35 to 65. The polyarthritis cutoff definition cohort consisted of the patients enrolled at the 20 centers that provided the largest sample of patients with extended oligoarthritis and RF-negative polyarthritis. The number of polyarthritis patients in each center ranged from 35 to 65.

Patient populations used for the validation of JADAS cutoffs. Patients in the EPOCA study who had oligoarthritis or polyarthritis according to the International League of Associations for Rheumatology categorization (17) (subclassified as above) and who were not part of the cutoff definition cohort were included in the cutoff validation cohort. In addition, we obtained longitudinal data from 2 randomized clinical trials. The first (the TRIMECA trial [Comparison of the Efficacy of Intraarticular Corticosteroid Therapy Administered Alone or in Combination with Methotrexate in Children with JIA]) was a multicenter randomized clinical trial conducted in Italy between July 7, 2009 and March 31, 2013, which compared intraarticular glucocorticoid injections alone versus intraarticular glucocorticoid injections plus methotrexate in the treatment of oligoarticular JIA in a study population of 207 patients (18). The second was a randomized controlled trial conducted between February 2004 and June 2006, which assessed the efficacy and safety of abatacept withdrawal versus continuation in 190 patients with JIA (19). In the latter data set, only patients with extended oligoarticular arthritis and RF-negative polyarthritis were considered for cutoff validation.

To assess predictive ability, a fourth sample of patients was obtained from PharmaChild (20), a multinational registry to assess the long-term safety and efficacy of medications in children with JIA. We included all patients who had undergone at least 4 prospective visits in the first year of observation and a complete clinical assessment at 2 years after enrollment.

Methods used to calculate the cutoffs. The methodology for the definition of rheumatoid arthritis disease activity states based on the Clinical Disease Activity Index (CDAI) and the Simplified Disease Activity Index (SDAI) (10) was adapted for the present study. The following 4 methods were used to identify cutoffs in the JADAS10 and cJADAS10 to distinguish the states of ID, MiDA, MoDA, and HDA in oligoarthritis and RF-negative polyarthritis: mapping, Youden index, 90% specificity, and agreement. The median of the values obtained with the 4 methods was retained as the cutoff for each disease activity state. For these analyses, we used the OptimalCutpoints package for R statistics, version 3.3.3 (21). This application computes optimal cut points for diagnostic tests or continuous markers and allows for selection of different approaches.

Mapping. For definition of the cutoff separating the states of ID and MiDA, the 75th percentile values of the JADAS10 and cJADAS10 in patients judged by their treating physician as having ID were retained. For definition of the cutoff separating the states of MiDA and MoDA, the 75th percentile values of the JADAS10 and cJADAS10 in patients judged as having ID or MiDA were retained. For definition of the cutoff separating the states of MoDA and HDA, the 25th percentile values of the JADAS10 and cJADAS10 in patients judged by their treating physician as having HDA were retained. Since for this analysis we considered it important to assign the same weight to each center regardless of the number of patients studied at the center, the cutoff values were retained separately for each center. The 20 values obtained for each cutoff were then averaged.

Youden index. The Youden index (J) identifies the maximum potential effectiveness of a biomarker through receiver operating characteristic (ROC) curve analysis. It is calculated with the formula $J = \max_c = (Se_c + Sp_c - 1)$, where $\max_c$ is the maximally effective cutoff, Se_c is the cutoff with the maximum sensitivity, and Sp_c is the cutoff with the maximum specificity. The cutoff that achieves this threshold is considered the best cutoff because it is the one that optimizes the discriminative ability of the evaluated parameter when sensitivity and specificity are weighted equally (22,23). For each of the 3 cutoffs, patients were divided into 2 mutually exclusive groups, coded as 0 or 1. For the cutoff separating ID from MiDA, the first group comprised patients judged as having ID by the attending physician and the second comprised patients judged as having MiDA, MoDA, or HDA; for the cutoff separating MiDA from MoDA, the first group comprised patients judged as having ID or MiDA and the second comprised patients judged as having MoDA or HDA; for the cutoff separating MoDA from HDA, the first group comprised patients judged as having ID, MiDA, or MoDA and the second comprised patients judged as having HDA.

Ninety percent fixed specificity. With the 90% fixed specificity method, the 3 values identifying the states of ID, MiDA, MoDA, and HDA were obtained by fixing the specificity at 90% in the ROC curve analysis and considering the attending physician rating as the gold standard. This approach was chosen to minimize the rate of misclassification of patients with moderate/high disease activity as having inactive disease (24,25).

Evaluation of agreement. The analysis of agreement was based on the kappa statistic, which assesses the agreement beyond chance between 2 dichotomous ratings, using OptimalCutpoints for R statistics. The first rating was obtained using all

Table 1. JADAS10 and cJADAS10 cutoff values for classification of disease activity in children with juvenile idiopathic arthritis (oligoarthritis or polyarthritis) according to 4 different methods for determining optimal cutoffs*

Diagnosis, disease state distinction, JADAS version	Method for optimal cutoff determination				Median#	Sensitivity of chosen cutoff value	Specificity of chosen cutoff value	AUC

# Median value among tentative cutoffs and chosen cutoff value.

possible JADAS10 and cJADAS10 values as hypothetical test criteria. To obtain the second rating, the categorical ratings from each attending physician (ID, MiDA, MoDA, or HDA) were dichotomized and were coded as 0 or 1, using the same approach as in the Youden index analysis. The software calculates the cutoff value with the highest kappa statistic.

Analyses performed to validate the cutoffs. Cutoff validation was based on assessment of discriminative and predictive ability. We tested whether the disease activity states according to the new cutoffs could discriminate 1) between patients in a cross-sectional sample with differing levels of various health outcomes, and 2) among different levels of response to a new treatment in 2 randomized clinical trials. Then, we tested the ability of JADAS10 and cJADAS10 states in the first year to predict clinically inactive disease at 2 years.

Ability to discriminate between different health states. In the EPOCA study, the median and interquartile range (IQR) level of pain on a 0–10-cm VAS (0 = no pain; 10 = maximum possible pain), the median and IQR count of joints with restricted function, the median level of physical function measured with the Juvenile Arthritis Functional Ability Scale (26) (range 0–45, where 0 is normal physical function), the percentage of parents who reported being not satisfied with current disease outcome, the percentage of patients with morning stiffness lasting >15 minutes, and the percentage of patients who were prescribed a new therapy for JIA at the study visit were compared across disease activity states defined by JADAS10 and cJADAS10 cutoffs. It was predicted that the values of all the above parameters would increase progressively from ID to HDA, although the changes in physical function and count of joints with restricted function were expected to be less pronounced as these indicators are affected by both disease activity and damage. Quantitative measures were compared by Kruskal-Wallis test with Dunn's post hoc test. Percentages were compared by chi-square test, with Bonferroni correction used for post hoc analysis.

Ability to discriminate among different levels of improvement. Patients at the 4-month visit in the open-label portion of the abatacept trial and at the 3-month visit in the TRIMECA trial were divided, according to the level of the American College of Rheumatology (ACR) Pediatric (Pedi) response (27), into 6 mutually exclusive groups: nonresponders, and ACR Pedi 30, 50, 70, 90, and 100 responders. For each level of response, we calculated the proportion of patients with ID, MiDA, MoDA, and HDA according to the new JADAS cutoffs. We expected that the proportion of patients with ID, MiDA, and MoDA would increase and that the proportion of patients with HDA would decrease when a higher level of improvement was met (moving from nonresponders to ACR Pedi 100 responders). We also expected that in both trials a higher proportion of patients would have had JADAS10 and cJADAS10 scores above the cutoffs for HDA cutoffs at the baseline visit.

Ability to predict future disease outcome. Among subjects in the PharmaChild registry, we compared the median and IQR number of visits with JADAS10 and cJADAS10 scores below the cutoffs for ID and MiDA and above the cutoffs for HDA in the first year of observation between patients who were and those who were not categorized as having CID according to the 2011 ACR JIA criteria (14) at 2 years. We also compared, using the same end point, the percentage of patients who had and those who did not have 2 or more visits with ID, MiDA, or HDA in the first year of observation. We expected that patients whose disease was clinically inactive at 2 years according to the ACR JIA criteria would have a higher number of visits with ID or MiDA and a lower number of visits with HDA in the first year. The inclusion of the state of MoDA was not considered meaningful for this analysis, because it was not expected that the number of visits in this intermediate state could predict the disease outcome.

Comparison with 2012–2014 cutoffs. The analyses described above were repeated using cutoffs published in 2012–2014 (11–13), and the statistical performance of the older versus the newer set of criteria was compared for each analysis (see below). The complete results of comparative validation of 2012–2014 cutoffs are presented in the Supplementary Appendix,

Table 2. Disease activity states based on the JADAS10 and cJADAS10, according to 2021 cutoffs and 2012–2014 cutoffs*

	2021 cutoffs		2012–2014 cutoffs	
Disease activity state	JADAS10	cJADAS10	JADAS10	cJADAS10
Oligoarthritis				
Inactive disease	≤1.4	≤1.1	≤1	≤1
Minimal disease activity	1.5–4	1.2–4	1.1–2	1.1–1.5
Moderate disease activity	4.1–13	4.1–12	2.1–4.2	1.51–4
High disease activity	>13	>12	>4.2	>4
Polyarthritis				
Inactive disease	≤2.7	≤2.5	≤1	≤1
Minimal disease activity	2.8–6	2.6–5	1.1–3.8	1.1–2.5
Moderate disease activity	6.1–17	5.1–16	3.9–10.5	2.51–8.5
High disease activity	>17	>16	>10.5	>8.5

* JADAS10 = Juvenile Arthritis Disease Activity Score 10; cJADAS10 = clinical JADAS10.

RESULTS

Definition of cutoffs. The cutoff selection cohort comprised 979 patients with oligoarthritis and 957 patients with polyarthritis. Demographic and clinical features of the patients are shown in Supplementary Table 1, on the *Arthritis & Rheumatology* website at http://onlinelibrary.wiley.com/doi/10.1002/art.41879/abstract.

The JADAS10 and cJADAS10 cutoffs obtained with the 4 different statistical approaches and the final 3 cutoffs, calculated as the median of the 4 values to define the 4 disease states (ID, MiDA, MoDA, and HDA) in oligoarthritis and polyarthritis, are shown in Table 1. Table 2 presents the comparison of the current proposed cutoffs (2021 cutoffs) with cutoffs published in 2012–2014 (11–13). All of the 2021 cutoffs were higher than the 2012–2014 cutoffs.

Validation of cutoffs. *Ability to discriminate between different health states.* A total of 1,859 and 2,155 patients with oligoarthritis and polyarthritis, respectively, from the EPOCA study were included in this analysis; demographic and clinical features are shown in Supplementary Table 1. The level of pain increased progressively from ID through HDA in both patient groups, based on either JADAS10 or cJADAS10 cutoffs (Figure 1). Likewise, the count of joints with restricted function and the physical function score worsened progressively throughout the same states ($P < 0.001$). However, Dunn's post hoc test revealed that among patients with oligoarthritis, only pain and physical function were different between all 4 disease activity states ($P < 0.001$ for all comparisons), whereas the count of joints with restricted function did not differ between patients with ID and patients with MiDA ($P = 0.18$ for JADAS10, $P = 0.14$ for cJADAS10). The proportion of parents not satisfied with illness outcome and the proportions of patients with morning stiffness and with newly prescribed medications at the time of the visit increased progressively from ID through HDA (Figure 2).

In the same data sets, using 2012–2014 cutoffs for oligoarthritis, the level of pain and functional ability and the count of joints with restricted function were not significantly different between patients with MiDA and patients with MoDA, for both the JADAS10 and the cJADAS10 (Figure 1 in the Supplementary Appendix, on the *Arthritis & Rheumatology* website at http://onlinelibrary.wiley.com/doi/10.1002/art.41879/abstract). Using the 2021 cutoffs, all comparisons in post hoc analyses of polyarthritis were significant.

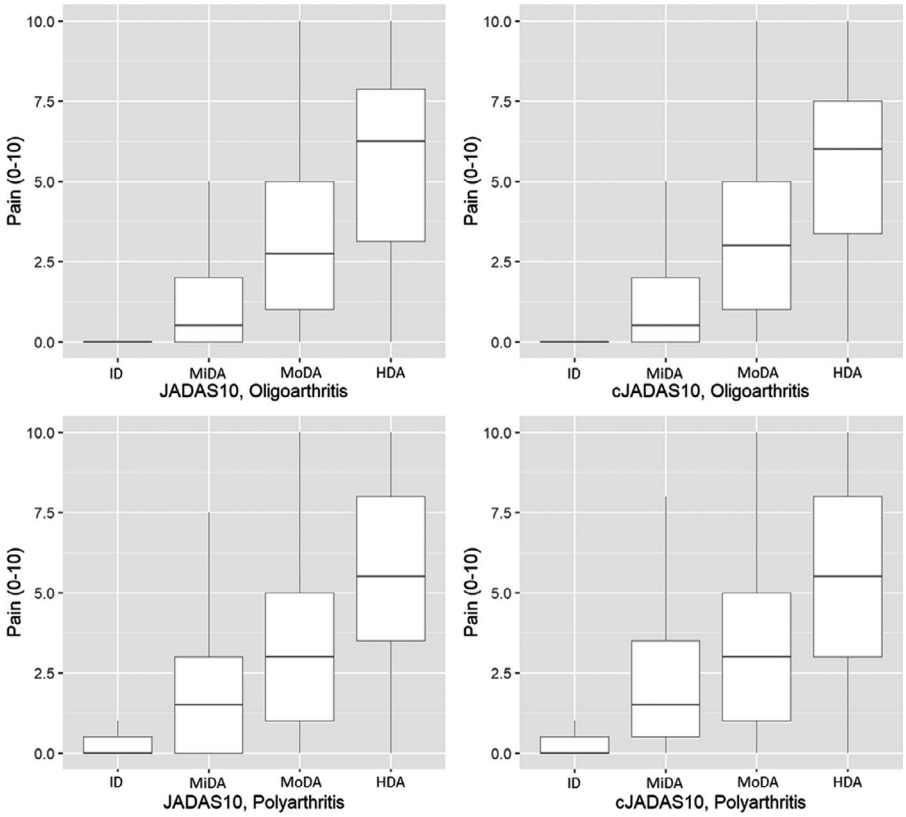

Figure 1. Comparison of the level of pain, measured on a 21-point 0–10 Likert scale, at visits (n = 1,908 for oligoarthritis and 2,489 for polyarthritis) in the Epidemiology, Treatment and Outcome of Childhood Arthritis study among patients with Juvenile Arthritis Disease Activity Score 10 (JADAS10)– and clinical JADAS10 (cJADAS10)–based inactive disease (ID), those with minimal disease activity (MiDA), those with moderate disease activity (MoDA), and those with high disease activity (HDA). Data are presented as box plots, where the boxes represent the 25th to 75th percentiles, the lines within the boxes represent the median, and the lines outside the boxes represent the range. $P < 0.001$ for comparison of disease states.

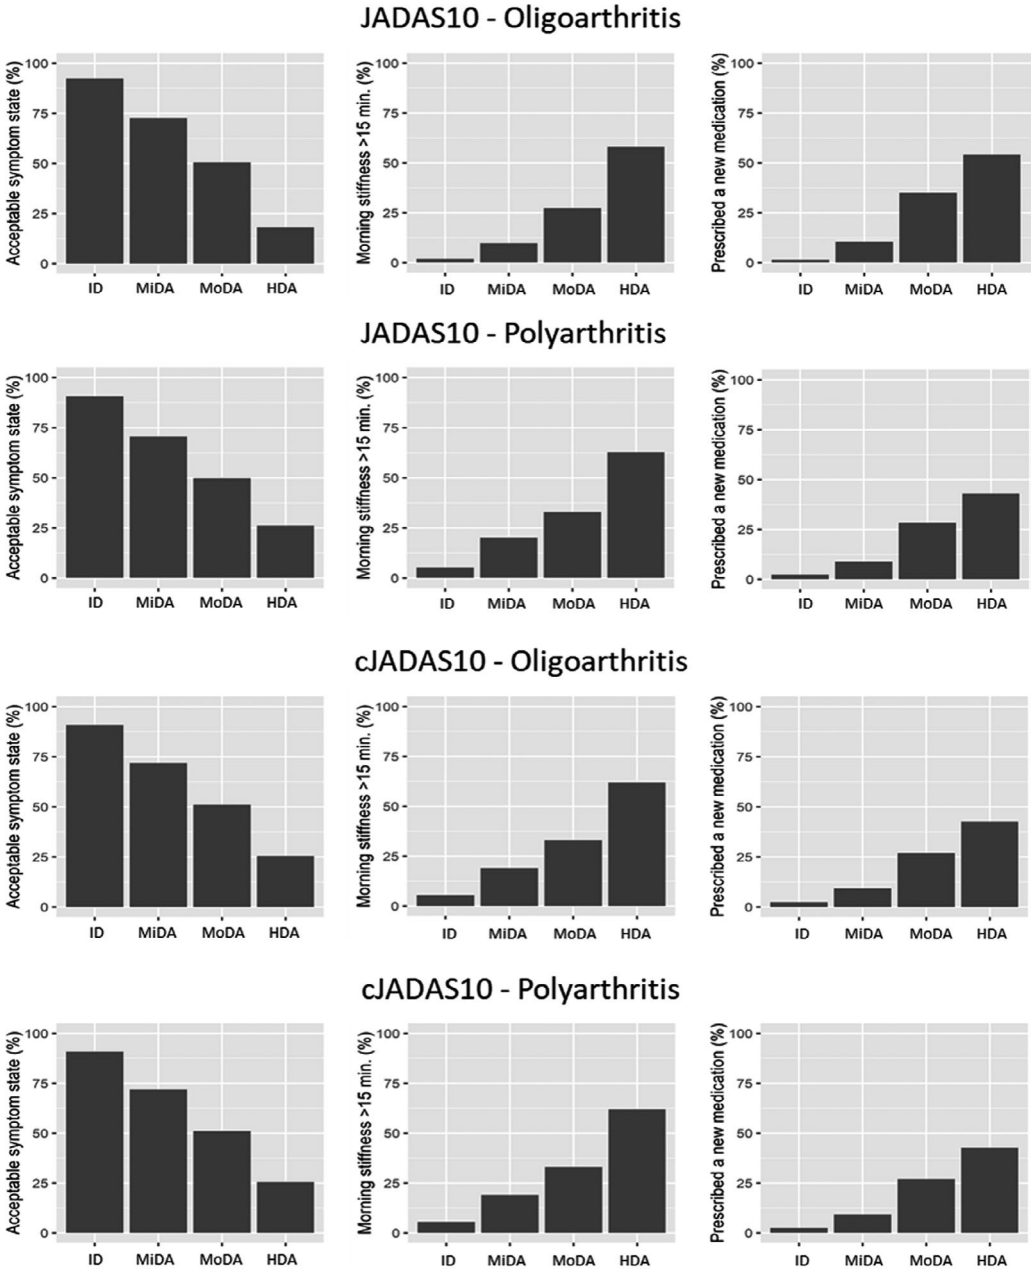

Figure 2. Percentage of patients whose parents described the patient's symptom status as acceptable, who had morning stiffness of >15 minutes, and who were prescribed a new medication for juvenile idiopathic arthritis at visits (n = 1,908 for oligoarthritis and 2,489 for polyarthritis) in the Epidemiology, Treatment and Outcome of Childhood Arthritis study among patients with Juvenile Arthritis Disease Activity Score 10 (JADAS10)– and clinical JADAS10 (cJADAS10)–based inactive disease (ID), those with minimal disease activity (MiDA), those with moderate disease activity (MoDA), and those with high disease activity (HDA). In post hoc analyses with Bonferroni correction, all comparisons were significant at $P < 0.001$ with the following exceptions: $P = 0.04$ for the comparison of morning stiffness frequency in oligoarthritis patients between the cJADAS10 states of MiDA and MoDA, and $P = 0.37$ for the comparison of the frequency of new therapy prescription in oligoarthritis patients between the cJADAS10 states of MiDA and MoDA.

In oligoarthritis and polyarthritis, the frequency of new medication prescription was not different between patients with ID and patients with MiDA according to 2012–2014 cutoffs for JADAS10 and cJADAS10. Additionally, in oligoarthritis, the frequency of morning stiffness was not different between patients with MiDA and patients with MoDA according to 2012–2014 cutoffs for JADAS10 and cJADAS10 (Figure 2 in the Supplementary Appendix).

Ability to discriminate among different levels of improvement. The analysis included 148 oligoarthritis patients enrolled in the TRIMECA trial and 99 polyarthritis patients included in the abatacept trial. In the TRIMECA trial, all patients who exhibited an ACR Pedi 30 response at 3 months met the JADAS10 cutoffs for MoDA, whereas none met the cutoffs for ID and MiDA; of the 51 patients who exhibited an ACR Pedi 100 response,

Table 3. JIA patients with JADAS10 and cJADAS10 below the cutoff for inactive disease, with JADAS10 and cJADAS10 below the cutoff for minimal disease activity, and with JADAS10 and cJADAS10 above the cutoff for high disease activity in at least 2 visits in the first year of PharmaChild registry participation, among those with and those without clinically inactive disease according to ACR criteria at 2 years*

Visits in the first year†	Active disease at 2 years (n = 44)	Clinically inactive disease at 2 years (n = 44)	*P*
≥2 with ID by JADAS10	12 (27.3)	37 (84.1)	<0.001
≥2 with ID by cJADAS10	13 (29.5)	38 (86.4)	<0.001
≥2 with MiDA by JADAS10‡	27 (61.4)	42 (95.5)	<0.001
≥2 with MiDA by cJADAS10‡	26 (59.1)	42 (95.5)	<0.001
≥2 with HDA by JADAS10	7 (15.9)	1 (2.3)	0.064
≥2 with HDA by cJADAS10	8 (18.2)	0 (0.0)	0.009

* Values are the number (%). JIA = juvenile idiopathic arthritis; JADAS10 = Juvenile Arthritis Disease Activity Score 10; cJADAS10 = clinical JADAS10; ACR = American College of Rheumatology; ID = inactive disease; MiDA = minimal disease activity; HDA = high disease activity.
† Only patients with at least 4 visits in the first year of PharmaChild registry participation were included.
‡ Including patients with ID.

65%, 98%, and 100% met the JADAS10 cutoffs for ID, MiDA, and MoDA, respectively (Supplementary Figure 1A, http://onlinelibrary.wiley.com/doi/10.1002/art.41879/abstract). Similar data were obtained with the cJADAS10 (Supplementary Figure 1B). Of note, 1 patient in whom ID was achieved according to the JADAS10 and cJADAS10 was considered a nonresponder according to the ACR Pedi definition, due to an increase in the number of joints with limitation and a worsening in the level of physical function. The percentages of patients with JADAS10 and cJADAS10 above the cutoffs for HDA at trial baseline were 49% and 51%, respectively.

In the abatacept trial, 0%, 6%, and 56% of the patients with an ACR Pedi 30 response at 4 months met the JADAS10 cutoffs for ID, MiDA, and MoDA, respectively (Supplementary Figure 1C, http://onlinelibrary.wiley.com/doi/10.1002/art.41879/abstract); of those who exhibited an ACR Pedi 70 response, 31%, 75%, and 100% met the JADAS10 cutoffs for ID, MiDA, and MoDA, respectively. Findings with the cJADAS10 were similar (Supplementary Figure 1D). The percentages of patients with JADAS10 and cJADAS10 scores above the cutoffs for HDA at trial baseline were 63% and 68%, respectively.

According to 2012–2014 cutoffs, at least 50% of the patients with an ACR Pedi 30 to ACR Pedi 90 response in the TRIMECA trial would be classified as having HDA. In the abatacept trial, the percentage of patients with MiDA among patients who were ACR Pedi 70 responders according to 2012–2014 cutoffs did not exceed 40% (Figure 3 in the Supplementary Appendix, http://onlinelibrary.wiley.com/doi/10.1002/art.41879/abstract).

Ability to predict future disease outcome. The PharmaChild longitudinal sample included 88 patients, 33 of whom had persistent oligoarthritis. Among the patients with CID (n = 44) and those without CID (n = 44) by ACR JIA criteria at 2 years, the median number of visits with a JADAS10 score below the cutoff for ID, a JADAS10 score below the cutoff for MiDA, and a JADAS10 score above the cutoff for HDA, respectively, in the first year was 4 (IQR 2–5), 5 (IQR 4–5), and 0 (IQR 0–0) in those whose disease was clinically inactive at 2 years, and 1 (IQR 0–2), 3 (IQR 1–4), and 0 (IQR 0–1) in those whose disease was not clinically inactive at 2 years ($P < 0.001$, $P < 0.001$, and $P = 0.031$, respectively). Similar results were obtained with the cJADAS10 (data not shown). Among the patients with CID according to the ACR criteria at 2 years, the percentage of visits in the first year in which the patient had ID or MiDA was higher, and the percentage in which the patient had HDA was lower, compared to the percentages among patients whose disease was active at 2 years (Table 3). Results from the same analysis performed using 2012–2014 cutoffs are shown in Table 1 in the Supplementary Appendix.

DISCUSSION

In this study, we defined cutoffs in the JADAS10 and cJADAS10 that correspond to the states of ID, MiDA, MoDA, and HDA in juvenile oligoarthritis and RF-negative polyarthritis, based on the subjective perception of disease activity level by pediatric rheumatologists from different regions of the world. We propose that the new cutoffs be called the 2021 JADAS10 and cJADAS10 cutoffs, to distinguish them from the previous cutoffs developed in 2012 and 2014 (11–13). Cutoff development was conducted using a large multinational data set comprising nearly 2,000 patients enrolled in 35 pediatric rheumatology centers located in 49 countries on 5 continents. The large sample size and the wide geographic distribution of the centers make the study findings likely generalizable to patients with various JIA phenotypes and treated with different approaches. Notably, the new cutoffs are closer to the JADAS thresholds identified by Swart et al for treatment escalation from a cohort of JIA patients seen at an academic center (28).

We considered it necessary to develop new cutoff values because previous JADAS and cJADAS cutoffs were developed

using formal criteria for CID (14) and MiDA (15) as reference standards, but both of these definitions comprise some JADAS components, making it difficult to avoid circular reasoning. Indeed, the definition of CID includes the count of joints with active arthritis, the physician global assessment of disease activity, and measurement of an acute-phase reactant. The definition of MiDA is centered on the count of joints with active arthritis, the physician global assessment of disease activity, and the parent/patient assessment of well-being. Another limitation of 2012–2014 cutoffs was the use of the physician's treatment decisions, collected retrospectively, as an external criterion. This approach did not take into account the fact that treatment changes could be driven by factors other than disease activity, such as drug intolerance or increased body weight. Furthermore, therapeutic choices may vary between physicians from different regions and according to their particular expertise and local availabilities of treatments.

For definition of the cutoffs, we adapted the methodology used by Aletaha et al (10) for the establishment of the CDAI and SDAI cutoffs. However, unlike that study, in which physicians rated multiple hypothetical patient profiles, we performed a more direct assessment by capturing disease activity ratings using actual patients. Because the proposed 2021 cutoffs are derived from real-life perception of patient disease activity by treating physicians, they may have greater face validity and practical relevance than the 2012–2014 cutoffs. The cutoff values were obtained by applying 4 different methods; of note, the tentative cutoffs yielded by agreement analysis were consistently higher than those yielded by different approaches, with the exception of the cutoff separating ID from MiDA. While the new cutoffs for distinguishing between ID and MiDA are very close to previous ones for oligoarthritis, they appear to be less stringent for polyarthritis. All cutoffs for the other disease activity states are notably higher in the new set.

The new cutoffs were validated using 4 different samples, including nearly 5,000 JIA patients. In cross-validation analyses, cutoff values differentiated well between levels of disease severity, as measured in terms of pain and count of joints with restricted function, and between patients who had or did not have morning stiffness or whose parents were satisfied or not satisfied with the outcome of the illness. In addition, the cutoffs revealed a strong ability to discriminate between different levels of ACR Pedi response in 2 randomized clinical trials. Notably, the cutoff values separating ID from MiDA in polyarthritis were met in a sizable proportion of cases only among patients with at least an ACR Pedi 70 response, which is in accordance with our previous findings that only an improvement in symptoms of at least 70% makes a substantial difference in disease status in patients with JIA (5). Nearly all ACR Pedi 100 responders with polyarthritis and the large majority with oligoarthritis met the cutoffs for ID. Finally, in the PharmaChild registry, achievement of the new cutoffs in the first year of observation was found to predict the attainment of disease remission at 2 years.

Our results should be interpreted in light of some potential caveats. The assessors were not provided any background information on the definition of the various disease states that could help to enhance standardization of assessments. Furthermore, although the wide geographic representation of the pediatric rheumatologists who provided their ratings is a strength of our study, it could be argued that perception of disease activity may vary between physicians practicing in different regions or with diverse expertise and treatment availability. However, the fact that the reported cutoffs were based on the judgment of physicians from a large number of countries may lead to their widespread acceptance and use and foster the harmonization of clinical assessment in JIA. In addition, we decided to limit our study only to oligoarthritis and RF-negative polyarthritis owing to the wide clinical homogeneity between these 2 JIA categories. The application of the new cutoffs in different JIA categories, and in particular to RF-positive patients, who are included in most clinical trials on polyarthritis, requires validation. Recently, a systemic JIA–specific version of the JADAS was developed and validated (29), and cutoffs specific to this tool are needed. Finally, it must be acknowledged that part of the validation analysis (predictive ability assessment and ability to discriminate among different levels of improvement) was performed in a smaller subset of patients.

The comparison of the newer versus the older sets of criteria showed a better discriminative ability with the 2021 cutoffs, particularly for oligoarthritis. Moreover, the disease activity states based on the new cutoffs appear more consistent with the response to treatment defined with the ACR Pedi criteria in 2 clinical trials. In the comparison of predictive ability, the performances of cutoffs for inactive disease were similar. Compared to use of the 2012–2014 cutoffs, the percentage of patients with active disease at 2 years was relevantly higher among those who had at least 2 visits with a JADAS score below the cutoff for MiDA in the first year according to the 2021 cutoffs. Among patients with HDA at ≥2 visits in the first year according to 2021 cutoffs, a lower proportion had clinically inactive disease at 2 years.

In conclusion, we have developed a new set of JADAS10 and cJADAS10 cutoffs for the different disease activity states in JIA, which were based on the subjective perception of the level of disease activity by a multinational sample of pediatric rheumatologists. In validation analyses, the cutoffs demonstrated a strong ability to discriminate between different levels of disease severity and treatment response and to predict the achievement of long-term disease remission. Future studies should assess the 2021 cutoffs in other prospective patient cohorts and compare their metrologic performances to those of the 2012–2014 cutoffs.

ACKNOWLEDGMENTS

We are grateful to all of the Paediatric Rheumatology International Trials Organisation EPOCA Study Group researchers and to Dr. Alyssa Dominique (Bristol Myers Squibb), for providing access to the data from the abatacept trial. We also thank Drs. Ngoc-Phoi Duong, Brigitte Bader-Meunier, Richard Mouy, Florence Aeschlimann, Chantal Job-Deslandre, Isabelle Melki, and Caroline Freychet and Thl Thanh Thao Truong and Ngoc-Bao Duong (Hôpital Necker-Enfants Malades) for data collection in France.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Consolaro had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Ferguson,[8] Harry Gewanter,[9] Jaime Guzman,[10] Jennifer Horonjeff,[11] Peter A. Nigrovic,[12] Michael J. Ombrello,[6] Murray H. Passo,[13] Matthew L. Stoll,[3] C. Egla Rabinovich,[14] Rayfel Schneider,[7] Olha Halyabar,[15] Kimberly Hays,[13] Amit Aakash Shah,[16] Nancy Sullivan,[17] Ann Marie Szymanski,[6] Marat Turgunbaev,[16] Amy Turner,[16] and James Reston[17]

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the health care provider in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes, but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision, as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The American College of Rheumatology is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To develop treatment recommendations for children with juvenile idiopathic arthritis manifesting as non-systemic polyarthritis, sacroiliitis, or enthesitis.

Methods. The Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions were developed and refined by members of the guideline development teams. A systematic review was conducted to compile evidence for the benefits and harms associated with treatments for these conditions. GRADE (Grading of Recommendations Assessment, Development and Evaluation) methodology was used to rate the quality of evidence. A group consensus process was conducted among the Voting Panel to generate the final recommendations and grade their strength. A Parent and Patient Panel used a similar consensus approach to provide patient/caregiver preferences for key questions.

Results. Thirty-nine recommendations were developed (8 strong and 31 conditional). The quality of supporting evidence was very low or low for 90% of the recommendations. Recommendations are provided for the use of nonsteroidal antiinflammatory drugs, disease-modifying antirheumatic drugs, biologics, and intraarticular and oral glucocorticoids. Recommendations for the use of physical and occupational therapy are also provided. Specific

Drs. Colbert and Ombrello's work was supported by the NIH (grants AR-041184 and AR-041198, respectively, from the Intramural Research Program of the National Institute of Arthritis and Musculoskeletal and Skin Diseases). Dr. Ferguson's work was supported by the NIH (grant AR-059-703). Dr. Nigrovic's work was supported by the Fundación Bechara.

[1]Sarah Ringold, MD, MS: Seattle Children's Hospital, Seattle, Washington; [2]Sheila T. Angeles-Han, MD, MSc, Daniel Lovell, MD, MPH: Cincinnati Children's Hospital Medical Center, University of Cincinnati, Cincinnati, Ohio; [3]Timothy Beukelman, MD, MSCE, Matthew L. Stoll, MD, PhD, MSCS:

recommendations for polyarthritis address general medication use, initial and subsequent treatment, and adjunctive therapies. Good disease control, with therapeutic escalation to achieve low disease activity, was recommended. The sacroiliitis and enthesitis recommendations primarily address initial therapy and adjunctive therapies.

Conclusion. This guideline provides direction for clinicians, caregivers, and patients making treatment decisions. Clinicians, caregivers, and patients should use a shared decision-making process that accounts for patients' values, preferences, and comorbidities. These recommendations should not be used to limit or deny access to therapies.

INTRODUCTION

Juvenile arthritis is one of the most common chronic diseases of childhood, with an estimated prevalence of 1 per 1,000 children (1–3). The term juvenile idiopathic arthritis (JIA) defines a heterogeneous collection of inflammatory arthritides of unknown etiology with onset prior to age 16 years and a minimum duration of 6 weeks, following the exclusion of other known causes of synovitis (4). Current International League of Associations for Rheumatology (ILAR) classification criteria divide JIA into 7 mutually exclusive categories defined by the number of joints involved, presence or absence of extraarticular manifestations, and presence or absence of additional markers including rheumatoid factor (RF) and HLA–B27 (4).

All forms of JIA are associated with decreased health-related quality of life and risk of permanent joint damage, and the disease may persist into adulthood, causing ongoing significant morbidity and impaired quality of life (5–13). A number of treatments are available, including nonsteroidal antiinflammatory drugs (NSAIDs), systemic and intraarticular glucocorticoids, and nonbiologic and biologic disease-modifying antirheumatic drugs (DMARDs). Prompt initiation of appropriate therapy is of critical importance in preventing permanent damage and improving outcomes. While earlier disease recognition and expanded treatment options have made good disease control a possibility for many patients, they have also made the decision-making regarding treatments more complex for physicians, caregivers, and patients.

The American College of Rheumatology (ACR) published initial recommendations for JIA in 2011 that provided guidance for the treatment of JIA and for the monitoring of select medical therapies, and an update in 2013 focused on the treatment of systemic arthritis (14,15). The ACR has subsequently transitioned from the RAND/UCLA Appropriateness Method used to generate these prior recommendations to the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology, which has the advantages of a more transparent decision-making process and well-defined criteria for moving from evidence to recommendation, including balancing benefits and harms and consideration of patient values and preferences while maintaining methodologic rigor (16).

The goal of this guideline project was to provide updated recommendations for juvenile non-systemic polyarthritis, sacroiliitis, and enthesitis, incorporating recently published data and utilizing the GRADE methodology. Recommendations for the treatment of chronic and acute JIA-associated uveitis were developed concomitantly and are presented separately (17).

METHODS

Methodology overview. This guideline followed the ACR guideline development process (http://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines). This process includes using the GRADE methodology (www.gradeworkinggroup.org) to rate the quality of the available evidence and to develop the recommendations (18–20). ACR policy guided disclosures and the management of conflicts of interest (participant disclosures are available at https://www.rheumatology.org/Portals/0/Files/JIA-Guideline-Disclosures.pdf). Submitted for publication August 31, 2018; accepted in revised form February 27, 2019.

at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract, describes the methods in detail.

Guideline development teams. This work involved 5 teams: 1) a Core Leadership Team, consisting of 4 pediatric rheumatologists, who supervised and coordinated the project and assisted with developing the scope of the project and initial Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions and drafting the manuscript; 2) a Literature Review Team, led by an experienced literature review consultant, which completed the literature search and data abstraction and rated the quality of evidence; 3) an Expert Panel, composed of 9 pediatric rheumatologists, who assisted with developing the scope of the project and drafting and refining the PICO questions; 4) a Voting Panel, consisting of 15 pediatric rheumatologists and 2 adult patients with JIA, who assisted with developing the scope of the project and refining the PICO questions and voted on the recommendations; and 5) a Parent and Patient Panel, consisting of 9 adult patients with JIA and 2 parents of children with JIA, who reviewed the collated evidence and provided input on their values and preferences within the context of a separate meeting. Supplementary Appendix 2 (available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract) presents rosters of the team and panel members. In accordance with ACR policy, the principal investigators and the literature review consultant were free of potential conflicts of interest, and in all teams, >50% of members were free of potential conflicts of interest.

PICO question development and importance of outcomes. The Core Leadership Team drafted the initial project scope, key principles, and examples of relevant PICO questions. The following topics were proposed to the guideline development groups for consideration: acute and chronic anterior uveitis, oligoarthritis, polyarthritis, systemic arthritis, sacroiliitis, enthesitis, and temporomandibular joint arthritis. PICO questions for each topic were developed and discussed at a face-to-face meeting during which the topics were refined. The project scope was subsequently limited to patients with non-systemic polyarthritis, sacroiliitis, and enthesitis, because these were deemed to be the most high-impact areas. The PICO questions for these topics were subsequently reviewed and further refined by the Expert and Voting Panels via e-mail.

Populations (Table 1). While the current ILAR classification criteria have been useful for identifying homogeneous groups of patients for research, more recent data suggest that these categories may not entirely reflect the underlying genetic and clinical heterogeneity of the disease or be relevant for guiding treatment decisions (20–22). For this reason, it was decided to base the current guideline on broad clinical phenotypes rather than ILAR categories, similar to the approach used for development of the 2011 guideline (15). The patient populations addressed in this guideline are defined below. The current recommendations are intended to address typical

Table 1. Terms and definitions*

Term	Definition
Polyarthritis population	Children with JIA and non-systemic polyarthritis (≥5 joints ever involved); may include children from ILAR JIA categories of polyarticular (rheumatoid factor positive or negative), extended oligoarticular, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis.
Risk factors	One or more of the following: positive rheumatoid factor, positive anti–cyclic citrullinated peptide antibodies, joint damage.
Moderate/high disease activity	Clinical Juvenile Disease Activity Score based on the cJADAS-10 >2.5.
Low disease activity	Clinical JADAS-10 ≤2.5 and ≥1 active joint.
Sacroiliitis population	Patients with active sacroiliitis who will most likely be classified within the ILAR categories of enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis, but may include patients in any of the ILAR JIA categories.
Active sacroiliitis	Prior or current magnetic resonance imaging findings consistent with sacroiliitis along with clinical examination findings consistent with sacroiliitis (e.g., pain with direct palpation of the sacroiliac joints) and/or patient-reported symptoms of inflammatory back pain.
Enthesitis population	Patients with enthesitis (inflammation at tendon-to-bone insertion sites) who will most likely be from the ILAR categories of enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis, but may include patients from any of the ILAR JIA categories.
Active enthesitis	Tenderness and/or swelling of the entheses determined to require medical treatment per the treatment provider.

* Disease activity (moderate/high and low) as defined by the clinical Juvenile Disease Activity Score based on 10 joints (cJADAS-10) is provided as a general parameter and should be interpreted within the clinical context. JIA = juvenile idiopathic arthritis. ILAR = International League of Associations for Rheumatology.

patients with the phenotype and may not be applicable to patients with uncommon features or highly refractory disease.

Polyarthritis. This group includes children with JIA and polyarthritis (≥5 joints ever involved) and may include children from different ILAR JIA categories but excludes children with systemic arthritis or sacroiliitis. These guidelines are not intended to be applicable to children with associated extraarticular manifestations (e.g., psoriasis, uveitis, inflammatory bowel disease) that may also influence treatment decisions. Given the heterogeneity of patients with JIA and polyarthritis, the Expert and Voting Panels initially categorized patients into treatment groups, using combinations of the following categories: 1) presence or absence of risk factors for disease severity and potentially a more refractory disease course, and 2) low disease activity versus moderate/high disease activity.

Risk factors were defined as the presence of one or more of the following: positive anti–cyclic citrullinated peptide antibodies, or joint damage. The Juvenile Arthritis Disease Activity Score (JADAS) was proposed as a means of categorizing disease activity, with the acknowledgment that a number of versions exist, and that validation is not fully complete and cutoff scores may change (23–27). A joint with inactive disease was defined using the ACR definition: presence of swelling (not due to currently inactive synovitis or to bony enlargement) or, if swelling is not present, limitation of motion accompanied by pain, tenderness, or both (28,29). The Voting Panel used the clinical JADAS based on 10 joints (cJADAS-10) and a cutoff of ≤2.5 versus >2.5 to define low versus high/moderate disease activity. Low disease activity was further defined as a cJADAS-10 of ≤2.5 and ≥1 joint with active disease to ensure that active arthritis was also present. Moderate and high disease activity were considered together, because it was thought that treatment approaches would be similar (30). The cJADAS-10 is a sum of the total active joint count (to a maximum of 10), physician's global assessment of disease activity (0–10 scale), and parent/patient's global assessment of well-being (0–10 scale). It was also acknowledged that one of the limitations of the JADAS is the lack of standardization of the physician's and parent's global assessments. It is therefore recommended that the JADAS be interpreted within the context of the clinical presentation rather than considered an absolute determinant of disease activity.

Because ultimately few data were available to support different treatment approaches based on the risk factors and disease activity categories, patients were often grouped together to provide a recommendation. The few instances in which the Voting Panel made differing recommendations based on disease activity or risk factors are explicitly noted.

Sacroiliitis. This group includes patients with active sacroiliitis who will most likely be classified within the ILAR categories of enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis but may include patients in any of the ILAR JIA categories. In addition to active sacroiliitis, patients may or may not have active peripheral joint disease and/or enthesitis to be included in this population. It is anticipated that patients with peripheral spondyloarthritis and no sacroiliitis would be treated according to the polyarthritis recommendations included in this update or existing JIA oligoarthritis treatment recommendations from the 2011 ACR JIA guideline (15), depending on the numbers of joints involved. For the purposes of this guideline, patients were considered to have active sacroiliitis if they had prior or current magnetic resonance imaging findings consistent with sacroiliitis along with clinical examination findings consistent with sacroiliitis (e.g., pain with direct palpation of the sacroiliac joints) and/or patient-reported symptoms of inflammatory back pain.

Enthesitis. This group is intended to include patients with enthesitis (inflammation at tendon-to-bone insertion sites) who will also most likely be from the ILAR categories of enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis but may include patients from any of the ILAR JIA categories. Patients may or may not have concomitant active peripheral arthritis or sacroiliitis to be included in this guideline, but the recommendations for enthesitis are intended to apply to patients with isolated enthesitis or with active enthesitis despite adequate control of their other disease manifestations. For the purposes of this guideline, active enthesitis is tenderness and/or swelling of the entheses determined to require medical treatment per the treating provider.

Interventions. The pharmacologic and nonpharmacologic therapies considered are listed in Table 2. Both intraarticular and oral glucocorticoids were considered. For the purposes of the recommendations, a bridging course of oral glucocorticoids was defined as a short course (<3 months) of oral glucocorticoids intended to control disease activity quickly during escalation of DMARD or biologic therapy, using the shortest possible duration and the lowest dose needed to control symptoms. The duration of bridging therapy would likely be primarily determined by the anticipated timing of onset of action of the other DMARD or biologic treatment(s). An optimal trial of methotrexate was considered to be 3 months; however, if no or minimal response was observed after 6–8 weeks, it was agreed that changing or adding therapy may be appropriate.

Outcomes. Outcomes were selected during the initial face-to-face scoping meeting and subsequently refined by online vote (Supplementary Appendix 3**,** available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract). Critical outcomes included disease activity, quality of life, joint damage, and serious adverse events. Pain was selected as an important outcome. While each of these outcomes was thought to be important in decision-making by the guideline development teams, they were not routinely reported across stud-

Table 2. Interventions included in the literature review*

Intervention	Name/type
NSAIDs	Any
DMARDs	Leflunomide, methotrexate, sulfasalazine, triple non–biologic DMARD (methotrexate, sulfasalazine, hydroxychloroquine)
Biologics	
TNFi	Adalimumab, etanercept, infliximab, golimumab†
Non-TNFi‡	Abatacept (CTLA-4Ig), tocilizumab (anti–interleukin-6 receptor), rituximab (anti-CD20)
Glucocorticoids	
Oral	Any
Intraarticular	Triamcinolone acetonide, triamcinolone hexacetonide, methylprednisolone acetate
Other interventions	Physical therapy
	Occupational therapy

* NSAIDs = nonsteroidal antiinflammatory drugs; DMARDs = disease-modifying antirheumatic drugs; TNFi = tumor necrosis factor inhibitor.
† Certolizumab was not included in the recommendations because no pediatric data were yet available.
‡ Evaluated for polyarthritis only.

ies. Disease activity and serious adverse events were the most consistently reported outcomes.

Literature searches, data abstraction, and rating the quality of evidence. Systematic searches of the published English-language literature included Ovid Medline, PubMed, Embase, and the Cochrane Library (including Cochrane Database of Systematic Reviews, Database of Abstracts of Reviews of Effects, Cochrane Central Register of Controlled Trials, and Health Technology Assessments) from the beginning of each database through June 12, 2017 (see Supplementary Appendix 4, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract); updated searches were conducted on October 13, 2017. DistillerSR software (https://distillercer.com/products/distillersr-systematic-reviewsoftware/) facilitated duplicate screening of literature search results. Supplementary Appendix 5, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract, shows the citation flow chart. Reviewers entered extracted data into RevMan software (http://tech.cochrane.org/revman) and evaluated the risk of bias of primary studies using the Cochrane risk of bias tool (http://handbook.cochrane.org/). RevMan files were exported into GRADEpro software to formulate a table showing the GRADE summary of findings (Supplementary Appendix 6, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract) for each PICO question (31).

When available, the evidence summaries included the benefits and harms for outcomes of interest across studies, the relative effect (95% confidence interval), the number of participants, and the absolute effects. GRADE criteria provided the framework for judging the overall quality of evidence (16). The Literature Review Team rated the quality of evidence for each critical and important outcome as high, moderate, low, or very low quality, taking into account limitations of study design, risk of bias, inconsistency, indirectness, imprecision, and other considerations. The overall quality listed in this report for a body of evidence (i.e., either an individual article or a group of articles) is not a statement about the methodologic quality of the study (or studies). Rather, the intention was to rate the article(s) in relation to the PICO question under consideration. As a result, a very well-conducted study might be rated lower in the evidence report. For example, if the population or intervention being studied does not completely match the population or intervention being examined by the PICO question, the evidence is downgraded for indirectness. The overall quality of evidence may also be downgraded due to imprecision in the effect estimate (e.g., wide confidence intervals or a low number of patients or events).

During the Voting Panel meeting, the panel also considered relevant data from adult studies, but these studies were not systematically searched or compiled in the evidence report. The Voting Panel was provided with a copy of the evidence report from the ACR/Spondylitis Association of America/Spondyloarthritis Research and Treatment Network 2015 Recommendations for the Treatment of Ankylosing Spondylitis and Nonradiographic Axial Spondyloarthritis as a reference (32) (https://www.rheumatology.org/Portals/0/Files/Axial-SpA-Guideline-Supplement-E.pdf).

Moving from evidence to recommendations. Each recommendation was made based on a consideration of the balance of relative benefits and harms of the treatment options under consideration, the quality of the evidence (e.g., confidence in the effect estimates), and patients' values and preferences, as per GRADE methodology. Discussion points and voting results from the Parent and Patient Panel meeting were presented during the Voting Panel meeting, as relevant. When the literature did not clearly guide recommendations, recommendations were based on the experience of the Voting Panel members (including physicians and the 2 patients present) as well as the results from the Parent and Patient Panel. Financial costs were not formally considered during the voting process.

Consensus building. The Voting Panel voted on the direction and strength of the recommendation related to each PICO question. Recommendations required a 70% level of

agreement; if 70% agreement was not achieved during an initial vote, the panel members held additional discussions before re-voting, including rewording of recommendations if needed, until consensus was attained (33). Discussion and iterative voting occurred until consensus was achieved. An additional round of voting was conducted online after the Voting Panel meeting to address questions that arose during preparation of the final recommendations. For each recommendation, a written explanation is provided, describing the reasons for this decision and conditions under which the alternative choice may be preferable, when relevant.

Moving from recommendations to practice. These recommendations are designed to help health care providers, caregivers, and patients engage in shared decision-making regarding treatment choices. Health care providers, caregivers, and patients must take into consideration not only clinical phenotype and level of disease activity but also comorbidities, response to and tolerance of prior therapies, patient's values and preferences, and patient's functional status and functional goals when choosing the optimal therapy for an individual patient at the given point in treatment.

RESULTS/RECOMMENDATIONS

How to interpret the recommendations (18–20)

1. A *strong* recommendation means that the Voting Panel was confident that the desirable effects of following the recommendation outweigh the undesirable effects (or vice versa), so the course of action would apply to all or almost all patients, and only a small proportion would not want to follow the recommendation. In some cases, strong recommendations were made even in the absence of moderate- or high-quality evidence based on Voting Panel experience and data from adult studies.
2. A *conditional* recommendation means that the Voting Panel believed that the desirable effects of following the recommendation probably outweigh the undesirable effects, so the course of action would apply to the majority of the patients, but some may not want to follow the recommendation. Because of this, conditional recommendations are particularly preference-sensitive and warrant a shared decision-making approach. Conditional recommendations were generally based on low- to very low–quality evidence. Most recommendations in this guideline are conditional.
3. For each recommendation, Supplementary Appendix 6 (available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23870/abstract) provides details regarding the PICO questions and the GRADE evidence tables. PICO questions were combined when possible to create simplified recommendations.

General recommendations for patients with JIA and polyarthritis (Table 3)

For this population, an initial set of general recommendations was made regarding NSAID, DMARD, intraarticular glucocorticoid, and biologic use. These general recommendations are intended to apply to the subsequent specific polyarthritis recommendations addressing these medications, because the recommendations were not anticipated to differ based on initial versus subsequent therapy, level of disease activity, or presence or absence of risk factors. For example, in PICO A.2 and A.3, methotrexate is conditionally recommended over leflunomide and sulfasalazine. It is intended that this recommendation apply to subsequent recommendations referring to DMARD therapy.

Each recommendation in this section is prefaced with the statement "In children and adolescents with JIA and active polyarthritis…"

PICO A.1. *NSAIDs are conditionally recommended as adjunct therapy*. This recommendation is conditional based on the very low quality of evidence and incorporation of patient and caregiver preferences, particularly concerns regarding medication adverse effects. In general, NSAIDs were thought to be appropriate for symptom management, particularly during initiation or escalation of therapy with DMARDs or biologics (34–36). It was acknowledged that NSAIDs are not appropriate as monotherapy for chronic, persistent synovitis.

PICO A.2–A.3. *Using methotrexate is conditionally recommended over leflunomide or sulfasalazine*.

Leflunomide. The quality of supporting evidence for this recommendation was moderate. The recommendation to favor methotrexate over leflunomide is due to the greater volume of data supporting the effectiveness of methotrexate. The Voting Panel also specifically noted the lack of data for the dosing, safety, and effectiveness of leflunomide in children younger than age 3 years and lack of long-term safety data for leflunomide in general for children with polyarthritis (37,38). In addition, there currently is no liquid form of this medication, which may make administration difficult, particularly in younger children.

Sulfasalazine. The recommendation for methotrexate over sulfasalazine is conditional, because the supporting evidence is of very low quality, there are no head-to-head comparison studies, and there are more data supporting the effectiveness of methotrexate. There were also concerns raised by the Voting Panel regarding the safety of sulfasalazine as compared to methotrexate, specifically the risk of Stevens-Johnson syndrome and bone marrow suppression (35,36).

Although methotrexate is conditionally recommended over each of these therapies, it is important to note that the Parent and Patient Voting Panel participants stated that they would want to be made aware of available alternatives to methotrexate, because

Table 3. General medication recommendations for children and adolescents with JIA and polyarthritis*

Recommendation	Level of evidence
Each recommendation is preceded by the phrase: *"In children and adolescents with JIA and active polyarthritis…"*	
NSAIDs	
• NSAIDs are conditionally recommended as adjunct therapy (PICO A.1).	Very low
DMARDs	
• Using methotrexate is conditionally recommended over leflunomide or sulfasalazine (PICO A.2, A.3).	Moderate (leflunomide); very low (sulfasalazine)
• Using subcutaneous methotrexate is conditionally recommended over oral methotrexate (PICO A.4).	Very low
Glucocorticoids	
• Intraarticular glucocorticoids are conditionally recommended as adjunct therapy (PICO A.5).	Very low
• Triamcinolone hexacetonide is ***strongly*** recommended over triamcinolone acetonide for intraarticular glucocorticoid injections (PICO A.6).	Moderate
• Bridging therapy with a limited course of oral glucocorticoids (<3 months) during initiation or escalation of therapy in patients *with high or moderate disease activity* is conditionally recommended (PICO A.7).† Bridging therapy may be of most utility in the setting of limited mobility and/or significant symptoms.	Very low
• Conditionally recommend *against* bridging therapy with a limited course of oral glucocorticoids (<3 months) in patients with *low disease activity* (PICO A.8).	Very low
• ***Strongly*** recommend *against* adding chronic low-dose glucocorticoid, irrespective of risk factors or disease activity (PICO A.9).	Very low
Biologic DMARDs	
• In children and adolescents with JIA and polyarthritis initiating treatment with a biologic (etanercept, adalimumab, golimumab, abatacept, or tocilizumab) combination therapy with a DMARD is conditionally recommended over biologic monotherapy (PICO A.10, A.11, A.12, A.13, A.14).	Very low (etanercept, golimumab); low (abatacept, tocilizumab); moderate (adalimumab)
• Combination therapy with a DMARD is ***strongly*** recommended for infliximab (PICO A.15).	Low
Physical therapy and occupational therapy	
• In children and adolescents with JIA and polyarthritis who have or are at risk of functional limitations, using physical therapy and/or occupational therapy is conditionally recommended (PICO A.16, PICO A.17).	Low (physical therapy); very low (occupational therapy)

* JIA = juvenile idiopathic arthritis; NSAIDs = nonsteroidal antiinflammatory drugs; PICO = Patient/Population, Intervention, Comparison, and Outcomes; DMARDs = disease-modifying antirheumatic drugs.
† A bridging course of oral glucocorticoids was defined as a short course (<3 months) of oral glucocorticoids intended to control disease activity quickly during the initiation or escalation of therapy. An adequate trial of methotrexate was considered to be 3 months. If no or minimal response is observed after 6–8 weeks, it was agreed that changing or adding therapy may be appropriate.

the adverse effects of methotrexate, particularly gastrointestinal intolerance, are very limiting for some children.

PICO A.4. *Using subcutaneous methotrexate is conditionally recommended over oral methotrexate*. This recommendation is conditional, because the supporting evidence is of very low quality, and patient preferences may guide the choice of route of administration (39–46). The strength of the recommendation also reflects Voting Panel experience, lack of certainty regarding differences in adverse event rates between the 2 routes of administration, consideration of data suggesting variable bioavailability of oral methotrexate (particularly at higher doses), and the goal of optimizing methotrexate effectiveness prior to escalating therapy (47,48).

PICO A.5. *Intraarticular glucocorticoids are conditionally recommended as adjunct therapy*. This recommendation is conditional given that the supporting evidence is of very low quality and was primarily generated in children with oligoarthritis, and given the variable parent and patient experiences and preferences regarding a procedure that may require sedation or be painful (49). In addition, intraarticular glucocorticoid injections may not be an appropriate treatment approach for large numbers of joints or joints that have been injected multiple times; escalation of systemic therapy may be preferred in these situations. The Voting Panel also suggested that intraarticular glucocorticoid injections be more strongly considered when arthritis is preventing ambulation or otherwise interfering with important daily activities and more prompt disease control is needed.

Table 4. General guidelines for the initial and subsequent treatment of children and adolescents with JIA and polyarthritis*

Recommendation†	Level of evidence
Each recommendation is preceded by the phrase: ***"In children and adolescents with JIA and active polyarthritis…"***	
Initial therapy	
All patients	
• Initial therapy with a DMARD is ***strongly*** recommended over NSAID monotherapy (PICO B.1).	Moderate
• Using methotrexate monotherapy as initial therapy is conditionally recommended over triple DMARD therapy (PICO B.2).	Low
Patients without risk factors:†	
• Initial therapy with a DMARD is conditionally recommended over a biologic (PICO B.3).	Low
Patients with risk factors:	
• Initial therapy with a DMARD is conditionally recommended over a biologic, recognizing that there are situations where initial therapy that includes a biologic may be preferred (PICO B.4). Initial biologic therapy may be considered for patients with risk factors and involvement of high-risk joints (e.g., cervical spine, wrist, or hip), high disease activity, and/or those judged by their physician to be at high risk of disabling joint damage.	Low
Subsequent therapy: Low disease activity (cJADAS-10 ≤2.5 and ≥1 active joint) For children receiving a DMARD and/or biologic:	
• Escalating therapy is conditionally recommended over no escalation of therapy (PICO B.5, B.6). Escalation of therapy may include: Intraarticular glucocorticoid injection(s), optimization of DMARD dose, trial of methotrexate if not done, and adding or changing biologic.	Very low
Subsequent therapy: Moderate/high disease activity (cJADAS-10 >2.5) If patient is receiving DMARD monotherapy:	
• Adding a biologic to original DMARD is conditionally recommended over changing to a second DMARD (PICO B.7).	Low
• Adding a biologic is conditionally recommended over changing to triple DMARD therapy (PICO B.8).	Low
If patient is receiving first TNFi (± DMARD):	
• Switching to a non-TNFi biologic (tocilizumab or abatacept) is conditionally recommended over switching to a second TNFi (PICO B.9). A second TNFi may be appropriate for patients with good initial response to their first TNFi (i.e., secondary failure).	Very low
If patient is receiving second biologic:	
• Using TNFi, abatacept, or tocilizumab (depending on prior biologics received) is conditionally recommended over rituximab (PICO B.10).	Very low

* Disease activity (moderate/high and low) as defined by the clinical Juvenile Disease Activity Score based on 10 joints (cJADAS-10) is provided as a general parameter and should be interpreted within the clinical context. TNFi = tumor necrosis factor (etanercept, adalimumab, infliximab, golimumab) (see Table 3 for other definitions).
† Risk factors include the presence of any of the following: positive anti–cyclic citrullinated peptide antibodies, positive rheumatoid factor, or presence of joint damage. An adequate trial of methotrexate was considered to be 3 months. If no or minimal response is observed after 6–8 weeks, it was agreed that changing or adding therapy may be appropriate. For the purposes of these recommendations, triple DMARD therapy is methotrexate, sulfasalazine, and hydroxychloroquine. The term biologic refers to TNFi, abatacept, or tocilizumab for each of the recommendations, with the exception of PICO B.10, which includes rituximab. Shared decision-making between the physician, parents, and patient, including discussion of recommended treatments and potential alternatives, is recommended when initiating or escalating treatment.

PICO A.6. *Triamcinolone hexacetonide is **strongly** recommended over triamcinolone acetonide for intraarticular glucocorticoid injections*. The quality of supporting evidence for this recommendation was moderate (50). This recommendation was further supported by observational studies showing improved outcomes with triamcinolone hexacetonide in oligoarticular JIA and rheumatoid arthritis (RA) (51,52). Voting panel members specifically noted their consistent and repeated observation of more complete and longer duration of clinical response without increased adverse effects with triamcinolone hexacetonide versus triamcinolone acetonide. The Parent and Patient Voting Panel also supported this judgment on the strength of the recommendation.

PICO A.7. *Bridging therapy with a limited course of oral glucocorticoids (<3 months) during initiation or escalation of therapy in patients with high or moderate disease activity is conditionally recommended*. This recommendation is conditional based on very low quality of supporting evidence and the known risks associated with systemic glucocorticoid treatment. Parents and patients agreed that bridging therapy was acceptable in this setting. Bridging therapy with glucocorticoids may have most utility

in the setting of high disease activity, limited mobility, and/or significant symptoms.

PICO A.8. *Conditionally recommend **against** bridging therapy with a limited course of oral glucocorticoids (<3 months) in patients with low disease activity*. The quality of evidence for this recommendation was very low. Intraarticular glucocorticoid injection was considered preferable in this setting.

PICO A.9. ***Strongly** recommend **against** adding chronic low-dose glucocorticoids, irrespective of risk factors or disease activity*. The quality of supporting evidence for this recommendation was very low. The recommendation was strong, however, given the known adverse effects of long-term systemic glucocorticoid treatment in children, particularly growth suppression, weight gain, osteopenia and cataracts, and availability of other treatment options. The Voting Panel agreed that in the setting of low disease activity, targeted joint injections may be more appropriate (PICO A.5). In the setting of moderate or high disease activity, escalating DMARD or biologic therapy is likely more appropriate.

PICO A.10–A.14. *In children and adolescents with JIA and polyarthritis initiating treatment with a biologic (etanercept, adalimumab, golimumab, abatacept, or tocilizumab), combination therapy with a DMARD is conditionally recommended over biologic monotherapy*. This recommendation is intended for patients initiating biologics for additional disease control and not intended for patients who may be tapering therapy due to inactive disease, for whom tapering or removal of the DMARD while continuing biologic therapy may be an appropriate strategy. The available evidence addresses combination therapy with methotrexate, with no evidence identified for other DMARDs. There was variability in the quality of supporting evidence for the medications, ranging from very low (etanercept, golimumab) to low (abatacept or tocilizumab) and moderate (adalimumab) (39,53–67). The potential benefit of methotrexate treatment for prevention of antidrug antibodies to adalimumab was included in the discussion for concomitant DMARD use with that medication (61). The overall recommendation is conditional based on the quality of supporting evidence and variable parent and patient preferences given the burden of taking multiple medications and concerns regarding methotrexate intolerance. The Voting Panel recognized that there may be situations in which biologic monotherapy is also acceptable, particularly in the setting of adequate disease control or methotrexate intolerance.

PICO A.15. *Combination therapy with a DMARD is **strongly** recommended for infliximab*. Using infliximab in combination with a DMARD was a strong recommendation despite the low quality of evidence, primarily given more extensive experience with the need for combination therapy to reduce the risk of antidrug antibody formation (68,69).

PICO A.16, A.17. *In children and adolescents with JIA and polyarthritis who have or are at risk for functional limitations, using physical therapy (PT) and/or occupational therapy (OT) is conditionally recommended*. This recommendation is conditional based on the low quality of supporting evidence for PT, very low level of evidence for OT, and Voting Panel experience (70,71).

Recommendations for the initial and subsequent treatment of JIA and polyarthritis (Table 4 and Figure 1)

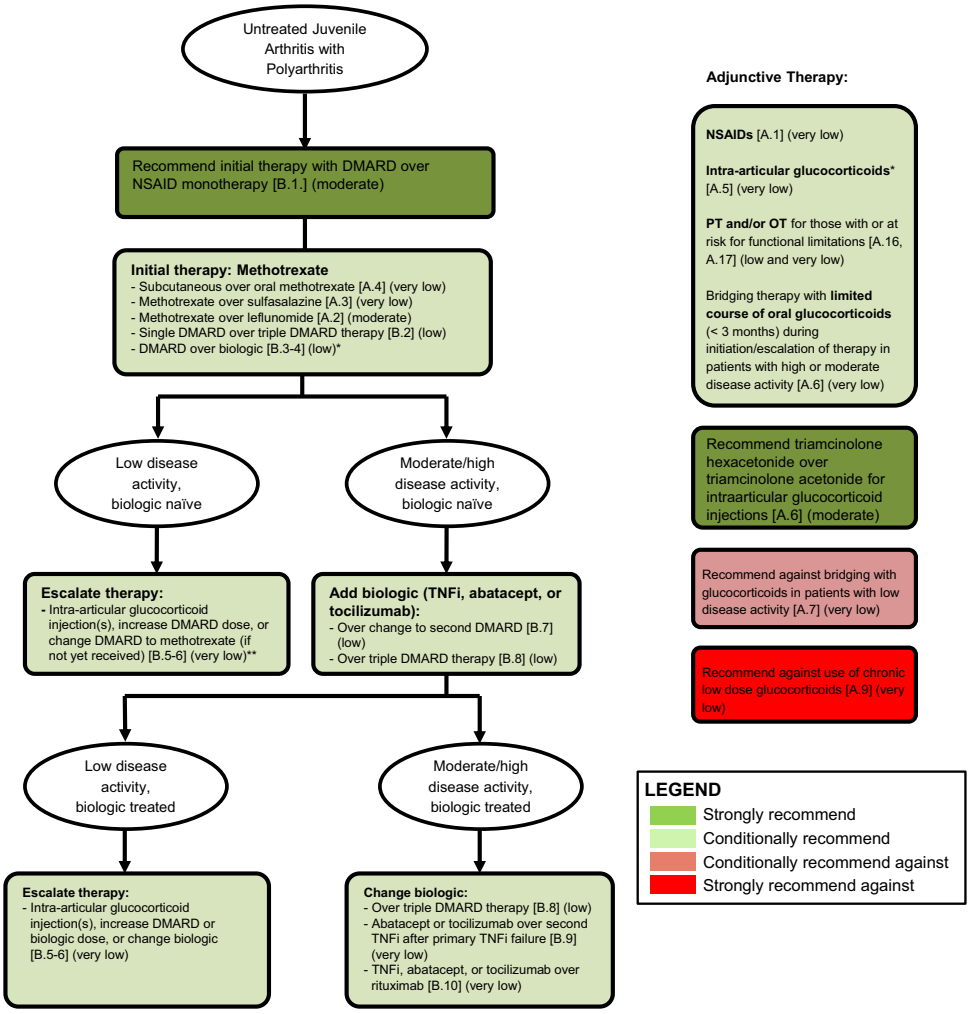
While the initial set of PICO questions for polyarthritis also included comparisons between specific biologics, these questions were discarded at the in-person Voting Panel meeting due to lack of evidence to guide decision-making in those scenarios. Although there is most experience with tumor necrosis factor inhibitors (TNFi) as the initial biologic, the class of initial biologic is not specified in the recommendations, again due to lack of comparative data, and the consideration that non-TNFi biologics may be preferred in certain scenarios based on patient-level factors (e.g., family history of demyelinating disease) and preferences. In the recommendations (see below), biologic therapy refers to TNFi, abatacept, or tocilizumab, with the exception of PICO B.9, in which rituximab is also addressed. Each recommendation in this section is prefaced with the statement "In children and adolescents with JIA and active polyarthritis…"

Initial therapy

PICO B.1 *Initial therapy with a DMARD is **strongly** recommended over NSAID monotherapy*. This recommendation is strong based on moderate quality of supporting evidence, known risk of permanent joint damage associated with ongoing, active disease, and Voting Panel experience (35,36,41).

PICO B.2. *Using methotrexate monotherapy as initial therapy is conditionally recommended over triple DMARD therapy*. The quality of evidence for this recommendation was low, based on the available trial being relatively small and not blinded (72). Parents and patients also expressed concerns about the burden of taking the 3 different medications, but they did state a preference to be informed about this treatment option.

PICO B.3. *For patients <u>without</u> risk factors, initial therapy with a DMARD is conditionally recommended over a biologic*. This recommendation is conditional based on low quality of supporting evidence and parent and patient differing preferences regarding the risks and benefits of DMARDs and biologics. While initial treatment with a biologic has been studied in TREAT-JIA (Trial of Early Aggressive Therapy in Polyarticular JIA) and ACUTE-JIA (Aggressive Combination Drug Therapy in Early Polyarticular JIA), the results were not thought to be conclusive enough to support



Untreated Juvenile Arthritis with Polyarthritis
Recommend initial therapy with DMARD over NSAID monotherapy [B.1.] (moderate)
Initial therapy: Methotrexate
- Subcutaneous over oral methotrexate [A.4] (very low)
- Methotrexate over sulfasalazine [A.3] (very low)
- Methotrexate over leflunomide [A.2] (moderate)
- Single DMARD over triple DMARD therapy [B.2] (low)
- DMARD over biologic [B.3-4] (low)*
Low disease activity, biologic naïve
Moderate/high disease activity, biologic naïve
Escalate therapy:
- Intra-articular glucocorticoid injection(s), increase DMARD dose, or change DMARD to methotrexate (if not yet received) [B.5-6] (very low)**
Add biologic (TNFi, abatacept, or tocilizumab):
- Over change to second DMARD [B.7] (low)
- Over triple DMARD therapy [B.8] (low)
Low disease activity, biologic treated
Moderate/high disease activity, biologic treated
Escalate therapy:
- Intra-articular glucocorticoid injection(s), increase DMARD or biologic dose, or change biologic [B.5-6] (very low)
Change biologic:
- Over triple DMARD therapy [B.8] (low)
- Abatacept or tocilizumab over second TNFi after primary TNFi failure [B.9] (very low)
- TNFi, abatacept, or tocilizumab over rituximab [B.10] (very low)
Adjunctive Therapy:
NSAIDs [A.1] (very low)
Intra-articular glucocorticoids* [A.5] (very low)
PT and/or OT for those with or at risk for functional limitations [A.16, A.17] (low and very low)
Bridging therapy with limited course of oral glucocorticoids (< 3 months) during initiation/escalation of therapy in patients with high or moderate disease activity [A.6] (very low)
Recommend triamcinolone hexacetonide over triamcinolone acetonide for intraarticular glucocorticoid injections [A.6] (moderate)
Recommend against bridging with glucocorticoids in patients with low disease activity [A.7] (very low)
Recommend against use of chronic low dose glucocorticoids [A.9] (very low)

Figure 1. Summary of primary recommendations for the initial and subsequent treatment of children with juvenile idiopathic arthritis (JIA) and active polyarthritis (see also Tables 3 and 4; for patients with sacroiliitis and/or enthesitis, see also Tables 5 and 6). The clinical Juvenile Arthritis Disease Activity Score based on 10 joints (cJADAS-10) was used to define low disease activity (≤2.5 with ≥1 active joint) versus moderate/high disease activity (>2.5). Although it is provided as a general parameter, the cJADAS-10 should be interpreted within the clinical context. An adequate trial of methotrexate was considered to be 3 months. If no or minimal response is observed after 6–8 weeks, it was agreed that changing or adding therapy may be appropriate. Shared decision-making between the physician, parents, and patient, including discussion of recommended treatments and potential alternatives, is recommended when initiating or escalating treatment. The Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions are shown in brackets, and quality of evidence is shown in parentheses. DMARD = disease-modifying antirheumatic drug; NSAID = nonsteroidal antiinflammatory drug; PT = physical therapy; OT = occupational therapy; TNFi = tumor necrosis factor inhibitor. *DMARD therapy (methotrexate, leflunomide, or sulfasalazine) over biologic recommendation for patients without and those with risk factors, although initial biologic therapy may be appropriate for some patients with risk factors and involvement of high-risk joints, high disease activity, and/or those judged by their physician to be at high risk of disabling joint damage. **Adding a biologic may be considered in biologic-naive patients with continued low disease activity after escalating therapy (not formally addressed in the guidelines).

biologics as initial therapy for low-risk patients (40,72). Of note, the majority of the Parent and Patient Panel voted against DMARDs as initial therapy, because a number of the participants had considerable adverse effects with methotrexate and had experienced better outcomes with biologics.

PICO B.4. *For patients with risk factors, initial therapy with a DMARD is conditionally recommended over a biologic, recognizing that there are situations where initial therapy that includes a biologic may be preferred*. This recommendation is conditional based on the low quality of supporting evidence and parent and patient differing preferences regarding the risks and benefits of DMARDs and biologics. While initial treatment with a biologic has been studied in TREAT-JIA and ACUTE-JIA, the results were not thought to be conclusive enough to support biologics as initial therapy (40,72). However, the Voting Panel acknowledged that biologics may be appropriate initial therapy for some patients *with risk factors* and involvement of high-risk joints (e.g.,

Table 5. Recommendations for the initial and subsequent treatment of children and adolescents with JIA and sacroiliitis*

Recommendation	Level of evidence
In children and adolescents with active sacroiliitis, treatment with an NSAID is ***strongly*** recommended over no treatment with an NSAID (PICO C.1).	Very low
In children and adolescents with active sacroiliitis despite treatment with NSAIDs:	
• Adding TNFi is ***strongly*** recommended over continued NSAID monotherapy (PICO C.2).	Low
• Using sulfasalazine for patients who have contraindications to TNFi or have failed more than one TNFi is conditionally recommended (PICO C.3).	Low
• ***Strongly*** recommend *against* using methotrexate monotherapy (PICO C.4).	Very low
Glucocorticoids	
In children and adolescents with active sacroiliitis despite treatment with NSAIDs:	
• Bridging therapy with a limited course of oral glucocorticoids (<3 months) during initiation or escalation of therapy is conditionally recommended (PICO C.5).† Bridging therapy may be of most utility in the setting of high disease activity, limited mobility, and/or significant symptoms.	Very low
• Intraarticular glucocorticoid injection of the sacroiliac joints as adjunct therapy is conditionally recommended (PICO C.6).	Very low
Physical therapy	
• In children and adolescents with sacroiliitis who have or are at risk for functional limitations, using physical therapy is conditionally recommended (PICO C.7).	Very low

* TNFi = tumor necrosis factor inhibitor (etanercept, adalimumab, infliximab, golimumab) (see Table 3 for other definitions).
† A bridging course of oral glucocorticoids was defined as a short course (<3 months) of oral glucocorticoids intended to control disease activity quickly during the initiation or escalation of therapy.

cervical spine, hip, and wrist), high disease activity, and/or for those judged by their physician to be at high risk of disabling joint damage. Of note, the majority of the Parent and Patient group voted against DMARDs as initial therapy, because a number of the participants had considerable adverse effects with methotrexate and had experienced better outcomes with biologics.

Subsequent therapy in patients with low disease activity (cJADAS-10 ≤2.5 and at least 1 active joint)

PICO B.5, B.6. *In patients with JIA and polyarthritis and low disease activity (cJADAS-10 ≤2.5 and at least 1 active joint) despite a DMARD or biologic, escalating therapy is conditionally recommended over no escalation of therapy*. This recommendation is conditional based on the very low quality of supporting evidence and parent and patient preferences regarding the risks and benefits of the treatment options. For this recommendation, escalating therapy is defined as any of the following: intraarticular glucocorticoid injection, increasing the DMARD or biologic dose (if not at optimal dosage), or changing biologic. Changing to an alternate DMARD (methotrexate) was suggested primarily for patients who had not yet received methotrexate and had not yet escalated to treatment with a biologic. Additional considerations included a degree of improvement while receiving current therapy

Table 6. Recommendations for the initial and subsequent treatment of children and adolescents with JIA and enthesitis*

Recommendation	Level of evidence
In children and adolescents with active enthesitis, NSAID treatment is ***strongly*** recommended over no treatment with an NSAID (PICO D.1).	Very low
In children and adolescents with active enthesitis despite treatment with NSAIDs:	
• Using a TNFi is conditionally recommended over methotrexate or sulfasalazine (PICO D.2, D.3).	Low
• Bridging therapy with a limited course of oral glucocorticoids (<3 months) during initiation or escalation of therapy is conditionally recommended (PICO D.4).† Bridging therapy may be of most utility in the setting of high disease activity, limited mobility, and/or significant symptoms.	Very low
Physical therapy	
• In children and adolescents with enthesitis who have or are at risk for functional limitations, using physical therapy is conditionally recommended (PICO D.5).	Very low

* TNFi = tumor necrosis factor inhibitor (etanercept, adalimumab, infliximab, golimumab) (see Table 3 for other definitions).
† A bridging course of oral glucocorticoids was defined a short course (<3 months) of oral glucocorticoids intended to control disease activity quickly during the initiation or escalation of therapy.

and the specific joint that was active. Synovitis preventing ambulation or otherwise interfering with important daily activities was identified as a factor that would guide more aggressive intervention (e.g., intraarticular glucocorticoid injection or adding/changing biologic).

Subsequent therapy in patients with moderate or high disease activity (cJADAS-10 >2.5)

PICO B.7. *In patients with JIA and polyarthritis and moderate or high disease activity despite DMARD monotherapy, adding a biologic to the original DMARD is conditionally recommended over changing to a second DMARD*. This recommendation was conditional based on the low quality of supporting evidence and parent and patient preferences regarding the risks and benefits of DMARDs and biologic medications (29,58,61,64,65,67,72–82).

PICO B.8. *In patients with JIA and polyarthritis and moderate or high disease activity receiving DMARD monotherapy, adding a biologic is conditionally recommended over changing to triple DMARD therapy*. The quality of evidence for this recommendation was low, based on the published pediatric trial being relatively small and not blinded (72). Although studies in RA have suggested that triple therapy is non-inferior to biologic therapy, the pediatric study showed improved outcomes for biologic therapy over triple DMARD therapy (83,84). This recommendation was also supported by Voting Panel concerns about adherence to the regimen and tolerability and parent and patient concerns about the burden of taking the 3 different medications.

PICO B.9. *In patients with JIA and polyarthritis and moderate or high disease activity receiving a first TNFi (with or without DMARD), switching to a non-TNFi biologic (tocilizumab or abatacept) is conditionally recommended over switching to a second TNFi*. This recommendation was conditional based on very low quality of supporting evidence and parent and patient preferences regarding the risks and benefits of biologics with different mechanisms of action (79,85). In making this recommendation, the Voting Panel also considered data from RA that have suggested better outcomes with switching to a non-TNFi biologic (86–88). The Voting Panel agreed that a second TNFi may be appropriate for patients who had a good initial response to their first TNFi (i.e., secondary failure), particularly failure due to the presence of suspected or measured antidrug antibodies to the first TNFi.

PICO B.10. *In patients with JIA and polyarthritis and moderate or high disease activity despite a second biologic, using a TNFi, abatacept, or tocilizumab (depending upon prior biologics received) is conditionally recommended over rituximab*. This recommendation was conditional based on very low quality of supporting evidence, Voting Panel member experience, and parent and patient preferences regarding the risks and benefits of biologics with different mechanisms of action. This recommendation was also supported by the availability of data from randomized clinical trials of tocilizumab and abatacept establishing their efficacy in JIA, which is lacking for rituximab (64,65,67). In addition, the article identified for the evidence report showed a higher rate of serious adverse events for rituximab compared to other biologics (78). The Voting Panel did discuss that rituximab may be considered earlier for RF-positive children based on data from RA, although the other 3 classes of biologics would still be primarily recommended (89).

Recommendations for the treatment of JIA and sacroiliitis (Table 5)

PICO C.1. *In children and adolescents with JIA and active sacroiliitis, treatment with an NSAID is **strongly** recommended over no treatment with an NSAID*. This recommendation was strong despite very low quality of supporting evidence in children, given the established utility of NSAIDs in adult spondyloarthritis and the analgesic effects of NSAIDs in children with other forms of arthritis. This recommendation is in alignment with the treatment recommendations for ankylosing spondylitis co-developed by the American College of Rheumatology/Spondylitis Association of America Spondyloarthritis Research and Treatment Network (32).

PICO C.2. *In children and adolescents with active sacroiliitis despite NSAIDs, adding a TNFi is **strongly** recommended over continued NSAID monotherapy*. Although the quality of supporting evidence in pediatrics for this recommendation was low, this recommendation is based on evaluation of both pediatric data and data from adult spondyloarthritis that include randomized controlled trials showing benefit (80,90–99).

PICO C.3. *In children and adolescents with active sacroiliitis despite NSAIDs, using sulfasalazine for patients who have contraindications to TNFi or have failed more than one TNFi is conditionally recommended*. This recommendation was conditional based on low quality of supporting evidence, particularly the relatively limited efficacy of sulfasalazine demonstrated in a randomized controlled trial in juvenile spondyloarthritis (100). However, it was considered as a potential option for patients with contraindications to TNFi and based on parent and patient considerations of the risks and benefits of biologics versus sulfasalazine. Sulfasalazine was also considered as an option for patients with adverse events associated with their initial TNFi that would be considered a class effect and who would therefore not be able to receive additional TNFi. Non-TNFi biologics

(e.g., interleukin-17 [IL-17] inhibitors) were not considered by the Voting Panel, because there are no published pediatric studies.

PICO C.4. *In children and adolescents with active sacroiliitis despite NSAIDs,* ***strongly*** *recommend against using methotrexate monotherapy*. Although the quality of supporting evidence for this recommendation was very low, this recommendation is based on data from adult spondyloarthritis suggesting lack of effectiveness (92,101–103). While we recommend against using methotrexate monotherapy as a treatment for sacroiliitis, methotrexate may have utility as adjunct therapy in patients with concomitant peripheral polyarthritis or to prevent the development of antidrug antibodies against monoclonal TNFi.

PICO C.5. *In children and adolescents with active sacroiliitis despite treatment with NSAIDs, bridging therapy with a limited course of oral glucocorticoids (<3 months) during initiation or escalation of therapy is conditionally recommended*. This recommendation is conditional based on very low quality of supporting evidence and known risks of glucocorticoid treatment. Bridging therapy with oral glucocorticoids may have the most utility in the setting of high disease activity, limited mobility, and/or significant symptoms.

PICO C.6. *In children and adolescents with active sacroiliitis despite treatment with NSAIDs, intraarticular glucocorticoid injection of the sacroiliac joints as adjunct therapy is conditionally recommended*. This recommendation was conditional based on very low quality of evidence and on varying parent and patient preferences regarding the procedure.

PICO C.7. *In children and adolescents with sacroiliitis who have or are at risk for functional limitations, using PT is conditionally recommended*. This recommendation was conditional based on the very low quality of supporting evidence and Voting Panel experience. It was also discussed that there may be a role for PT and activity modification in specifically identifying and reducing mechanical factors contributing to microtrauma and repetitive stress that could potentially contribute to disease activity in these patients (104).

Recommendations for the treatment of JIA and enthesitis (Table 6)

PICO D.1. *In children and adolescents with JIA and active enthesitis, NSAID treatment is* ***strongly*** *recommended over no treatment with an NSAID*. This recommendation is strong despite the very low quality of supporting evidence based on Voting Panel experience, established analgesic effects, and data from adult disease showing benefit (105).

PICO D.2, D.3. *In children and adolescents with JIA and active enthesitis despite treatment with NSAIDs, using a TNFi is conditionally recommended over methotrexate or sulfasalazine*. This recommendation is conditional based on the low quality of supporting evidence. While TNFi is preferred, the Voting Panel discussed that a trial of methotrexate or sulfasalazine may be warranted for patients with contraindications to TNFi, patients with mild enthesitis, and patients with concomitant active peripheral polyarthritis (80,90–95,100).

PICO D.4. *In children and adolescents with JIA and chronic active enthesitis despite treatment with NSAIDs, bridging therapy with a limited course of oral glucocorticoids (<3 months) during initiation or escalation of therapy is conditionally recommended*. This recommendation is conditional based on very low quality of supporting evidence and known risks of glucocorticoid treatment in the pediatric population. Bridging therapy with glucocorticoids may have most utility in the setting of high disease activity, limited mobility, and/or significant symptoms.

PICO D.5. *In children and adolescents with JIA and enthesitis who have or are at risk for functional limitations, using PT is conditionally recommended*. This recommendation was conditional based on very low quality of evidence and Voting Panel experience.

DISCUSSION

This guideline includes 39 recommendations for the treatment of children with JIA and non-systemic polyarthritis, sacroiliitis, and enthesitis. The quality of most of the available evidence was low or very low in relation to the relevant clinical PICO questions, resulting in 31 of the recommendations being conditional.

These recommendations provide an updated approach to the treatment of children with non-systemic polyarthritis, sacroiliitis, and enthesitis. These populations were chosen for this guideline because they have been the focus of significant recent research, with better delineation of the underlying biology and additional treatments available since the 2011 ACR recommendations for JIA. Similar to the 2011 recommendations, this guideline defined patient populations by clinical phenotypes rather than ILAR categories. This decision was made because data continue to suggest that current JIA categories may not accurately reflect the underlying biology and anticipated treatment responses in patients with juvenile arthritis.

This guideline differs from the 2011 recommendations in the definitions of risk factors and disease activity assessment used to generate patient scenarios. Although PICO questions were initially stratified by risk factors and disease activity, the Voting Panel ultimately determined that in most scenarios there were not sufficient data to recommend different treatments for these

patients, and recommendations were frequently combined. Another important difference from the 2011 recommendations is that initial NSAID monotherapy for polyarthritis is no longer recommended, given the established benefits of early initiation of DMARD treatment. Individual PICO questions for each biologic were initially considered but subsequently dropped by the Voting Panel, given mostly equivalent data for safety and efficacy between the biologics and lack of head-to-head comparisons. The exceptions were that TNFi are specifically recommended for sacroiliitis, and rituximab is considered only after TNFi, abatacept, and tocilizumab have been tried. This approach has resulted in a simplified treatment algorithm. Last, this guideline also includes recommendations for escalating care in the setting of low disease activity, highlighting the importance of achieving and maintaining complete disease control, which was not previously addressed.

The current recommendations also differ from the 2011 recommendations in that they were developed using GRADE methodology instead of the RAND/UCLA Appropriateness Method. The systematic, transparent, and explicit process of developing recommendations through GRADE is a major feature accelerating its adoption by professional groups internationally (www.gradeworkinggroup.org). Important features of this method are 1) specification of the patient groups, interventions, competing alternatives, and outcomes so that each recommendation is clearly focused on a particular clinical situation; 2) grading of the quality of evidence; and 3) basing the strength of recommendations on the quality of evidence, balance of benefits and harms, and patient values and preferences for different treatment options. This guideline considered parent and patient preferences assessed by a separate Parent and Patient Panel. Primary themes that emerged from that discussion were: 1) the importance of shared decision-making; 2) the importance of parents and patients receiving information regarding not only the preferred medication or intervention but also the alternatives; and 3) parent/patient support of earlier consideration of biologics given their experiences with decreased adverse effects and improved quality of life with the use of these medications relative to their experiences with methotrexate. Although this was a select group of parents and patients, and their experiences may not be representative of all patients, their discussion provided an important perspective that was incorporated into the Voting Panel discussion and voting.

A topic of particular debate among the Voting Panel was the appropriateness of the use of biologics as initial therapy in children with polyarthritis, particularly for those with risk factors. Ultimately, non–biologic DMARD therapy was recommended, but it was noted that there may be some patients for whom initial biologic therapy is indicated. This remains an area of active research, and currently ongoing studies may better clarify which patients are most likely to benefit from initial biologic therapy. Importantly, studies in pediatrics are underway or planned for a number of new medications, including JAK inhibitors and IL-17 and IL-12/23 inhibitors, and these medications may become useful additions as treatment options for JIA, particularly in patients with sacroiliitis for whom limited options exist. Other studies currently underway in parallel adult diseases may also inform the optimal treatment of enthesitis and the treatment of peripheral spondyloarthritis. Future guideline efforts may determine where these treatments fit into the treatment algorithm and will incorporate the results from the ongoing studies once complete.

Nonpharmacologic interventions addressed in this guideline included PT and OT. In each case, very limited data were identified, and future research in these modalities will be helpful in identifying patients most likely to benefit from these interventions and which modalities have most effectiveness for particular clinical scenarios.

The cJADAS-10 was used to provide general disease activity parameters for defining low and moderate/high disease activity. However, this is not intended to be prescriptive and should be interpreted within the overall clinical context. Furthermore, because the JADAS is a relatively new disease activity measurement tool, new cutoffs may be proposed, since additional data are generated that may accommodate different numbers of active joints or other levels of physician's or parent's global assessment. The identification of valid and practical disease activity measures in JIA remains an important research agenda in pediatric rheumatology. Nevertheless, it was agreed by the Voting Panel that treatment should be escalated in patients with even 1 active joint. Formal recommendations regarding disease activity measurement tools, cutoffs, and monitoring intervals were not specifically addressed in this guideline. Last, the management of inactive disease and the tapering and withdrawal of medications for patients with inactive disease are not addressed in this guideline but will be important for future guidelines.

Because the quality of evidence was overall low and most recommendations were conditional, clinicians, caregivers, and patients should use a shared decision-making process when considering these recommendations. While these recommendations are intended to address common clinical situations, all treatment decisions must be individualized, with consideration of the unique aspects of each patient's presentation, medical history, and preferences.

ACKNOWLEDGMENTS

We thank Alexei Grom, MD, Ron Laxer, MD, FRCP, Mindy Lo, MD, PhD, Sampath Prahalad, MD, MSc, Meredith Riebschleger, MD, Angela Byun Robinson, MD, MPH, Grant Schulert, MD, PhD, Heather Tory, MD, and Richard Vehe, MD, for serving on the Expert Panel. We thank Suzanne Schrandt with the Arthritis Foundation for her involvement throughout the guideline development process. We thank our patient representative for adding valuable perspectives. We thank Liana Fraenkel, MD, MPH, for leading the Patient Panel meeting, as well as the patients and

parents who participated in this meeting: Linda Aguiar, Jake Anderson, Samantha Bell, Julianne Capron, Stephanie Dodunski, Holly Dwyer, Stephanie Kweicein, Carolina Mejia Pena, and Nikki Reitz, LCSW. We thank the American College of Rheumatology staff, including Regina Parker for assistance in organizing the face-to-face meetings and coordinating the administrative aspects of the project, and Robin Lane for assistance with manuscript preparation. We thank Janet Waters for help in developing the literature search strategy and performing the literature search and updates, and Janet Joyce for peer-reviewing the literature search strategy.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Ringold had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception and design. Ringold, Angeles-Han, Beukelman, Lovell, Cuello, Becker, Colbert, Feldman, Ferguson, Gewanter, Guzman, Horonjeff, Nigrovic, Schneider, Halyabar, Turner, Reston.

Acquisition of data. Ringold, Angeles-Han, Beukelman, Lovell, Cuello, Becker, Colbert, Feldman, Ferguson, Gewanter, Guzman, Horonjeff, Nigrovic, Ombrello, Passo, Rabinovich, Schneider, Halyabar, Hays, Shah, Sullivan, Szymanski, Turgunbaev, Reston.

Analysis and interpretation of data. Ringold, Angeles-Han, Beukelman, Lovell, Cuello, Becker, Colbert, Feldman, Ferguson, Gewanter, Guzman, Horonjeff, Nigrovic, Ombrello, Passo, Stoll, Schneider, Halyabar, Hays, Shah, Sullivan, Turgunbaev, Reston.

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for particular patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the health care provider in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The American College of Rheumatology is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To develop recommendations for the screening, monitoring, and treatment of uveitis in children with juvenile idiopathic arthritis (JIA).

Methods. Pediatric rheumatologists, ophthalmologists with expertise in uveitis, patient representatives, and methodologists generated key clinical questions to be addressed by this guideline. This was followed by a systematic literature review and rating of the available evidence according to the GRADE (Grading of Recommendations Assessment, Development and Evaluation) methodology. A group consensus process was used to compose the final recommendations and grade their strength as conditional or strong.

Results. Due to a lack of literature with good quality of evidence, recommendations were formulated on the basis of available evidence and a consensus expert opinion. Regular ophthalmic screening of children with JIA is recommended because of the risk of uveitis, and the frequency of screening should be based on individual risk factors. Regular ophthalmic monitoring of children with uveitis is recommended, and intervals should be based on ocular examination findings and treatment regimen. Ophthalmic monitoring recommendations were strong primarily because

Angeles-Han, MD, MSc, Daniel Lovell, MD, MPH: Cincinnati Children's Hospital Medical Center, University of Cincinnati, Cincinnati, Ohio; [2]Sarah Ringold, MD, MS: Seattle Children's Hospital, Seattle, Washington; [3]Timothy Beukelman, MD, MSCE, Matthew L. Stoll, MD, PhD, MSCS: University

of concerns of vision-threatening complications of uveitis with infrequent monitoring. Topical glucocorticoids should be used as initial treatment to achieve control of inflammation. Methotrexate and the monoclonal antibody tumor necrosis factor inhibitors adalimumab and infliximab are recommended when systemic treatment is needed for the management of uveitis. The timely addition of nonbiologic and biologic drugs is recommended to maintain uveitis control in children who are at continued risk of vision loss.

Conclusion. This guideline provides direction for clinicians and patients/parents making decisions on the screening, monitoring, and management of children with JIA and uveitis, using GRADE methodology and informed by a consensus process with input from rheumatology and ophthalmology experts, current literature, and patient/parent preferences and values.

INTRODUCTION

Uveitis is the most common extraarticular manifestation of juvenile idiopathic arthritis (JIA) and can be a chronic or acute disease. Chronic anterior uveitis (CAU) develops in 10–20% of children with JIA, is usually asymptomatic, and there is rarely external evidence of inflammation (1,2). Acute anterior uveitis (AAU) is a distinctly different form of uveitis. It is typically associated with HLA–B27 and occurs in children with spondyloarthritis (i.e., those with enthesitis-related or psoriatic arthritis). AAU differs from CAU in that AAU is episodic, unilateral, characterized by the sudden onset of erythema, pain, and photophobia, and generally does not require systemic treatment (3).

Uncontrolled CAU can lead to sight-threatening complications such as synechiae, cataracts, and glaucoma in 25–50% and vision loss in 10–20% of children with uveitis (2,4–6). Early detection through regular ophthalmic screening with timely and appropriate treatment can improve visual outcomes and prevent complications (5,7).

Because CAU is often asymptomatic until ocular complications arise, the American Academy of Pediatrics (AAP) published recommendations in 2006 for routine ophthalmic screening in children with arthritis (8). These recommendations were based on an older arthritis nomenclature and did not include uveitis screening in all JIA categories such as psoriatic, enthesitis-related, and undifferentiated arthritis. To fill this gap, in 2012, Heiligenhaus and colleagues from the German Uveitis in Childhood Study Group ("German recommendations") proposed ophthalmic screening schedules based on the International League of Associations for Rheumatology (ILAR) JIA classification scheme (9). These 2 publications, however, did not address the monitoring of children with an established diagnosis of uveitis or the treatment of uveitis. Thus, recommendations for both monitoring and treatment of uveitis in children with JIA are needed.

Initial treatment of children with JIA-associated uveitis typically includes topical glucocorticoids. In those who are refractory to or dependent on topical glucocorticoids, there are no accepted North American guidelines for the use of systemic immunosuppressive therapy. Methotrexate is the usual first-line systemic immunosuppressive agent, followed by tumor necrosis factor inhibitor (TNFi) biologics, particularly the monoclonal antibodies infliximab and adalimumab (10). Despite the frequency with which these drugs are used for uveitis, only 1 large randomized controlled trial (RCT) studying children with JIA-associated uveitis has been published (11). Guidance is needed for the acceptable duration and frequency of topical glucocorticoids prior to initiation of nonbiologic disease-modifying antirheumatic drugs (DMARDs) and systemic biologic therapy, and for the approach to initiation, escalation, and modification of systemic therapy. Optimization of treatment strategies is crucial to improve vision outcomes.

Submitted for publication August 31, 2018; accepted in revised form February 27, 2019.

To address this need, the American College of Rheumatology (ACR) and the Arthritis Foundation (AF) convened expert panels of pediatric rheumatologists and ophthalmologists to develop the first ACR/AF recommendations for the screening, monitoring, and treatment of JIA-associated CAU and AAU. Recognizing the importance of close collaboration and communication between pediatric rheumatologists and ophthalmologists, this guideline was developed in collaboration with experts from both specialties. Patient and parent panels also provided input. Overall, clinicians, parents, and patients should use a shared decision-making process that considers patients' preferences and values. Recommendations for the treatment of children with JIA manifesting as non-systemic polyarthritis, sacroiliitis, and enthesitis were developed concomitantly and are presented separately (12).

METHODS

Methodology overview. This guideline followed the ACR guideline development process (http://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines). This process uses the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) methodology (www.gradeworkinggroup.org) to rate the quality of the available evidence and to develop the recommendations (13–15). ACR policy guided disclosures and the management of potential conflicts of interest (participant disclosures are available at https://www.rheumatology.org/Portals/0/Files/JIA-Guideline-Disclosures.pdf). Supplementary Appendix 1 (available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23871/abstract) presents the full methods in detail.

Guideline development teams. This work involved 5 groups: 1) a Core Leadership Team, consisting of 4 pediatric rheumatologists, supervised and coordinated the project and drafted the clinical questions and manuscript; 2) a Literature Review Team, led by an experienced literature review consultant, completed the literature search and data abstraction; 3) an Expert Panel, composed of 9 pediatric rheumatologists and 1 ophthalmologist with expertise in the management of uveitis in children, developed the clinical Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions and decided on the scope of the guideline project; 4) a Voting Panel, including 15 pediatric rheumatologists, 2 ophthalmologists, both of whom were uveitis specialists, and 2 adult

Table 1. Terms, definitions, and medication interventions*

Terms/medications	Definition/name
Terms	
Controlled uveitis	Inactive OR grade <1+ anterior chamber cells without new complications due to active inflammation per Standardization of Uveitis Nomenclature criteria†
Complications due to active inflammation‡	New development of peripheral anterior synechiae, posterior synechiae, inflammatory membranes, or cystoid macular edema
Additional signs of active inflammation	Fresh keratic precipitates, increased flare, and hypotony
Complications representing cumulative damage	Cataract, glaucoma/elevated intraocular pressure, hypotony, or sequelae of keratic precipitates (hyalinized spots or ghost keratic precipitates)§
Loss of control‡	Increase of anterior chamber cells to grade 1+ or more or new signs of inflammation/complications of inflammation†
New uveitis activity	No history of prior uveitis or loss of control of previously controlled uveitis
Systemic therapy	Nonbiologic DMARDs and biologics
Medications included in the guideline	
Glucocorticoids	Topical eye drops
	Systemic (all oral)
Nonbiologic DMARDs	Methotrexate
	Leflunomide
	Mycophenolate
	Cyclosporine
Biologic DMARDs	Monoclonal TNF inhibitor (adalimumab, infliximab)
	Etanercept
	Abatacept
	Tocilizumab

* DMARDs = disease-modifying antirheumatic drugs; TNF = tumor necrosis factor.
† Grade 1+ anterior chamber cells = 6–15 cells per field in a 1-mm × 1-mm slit beam.
‡ Loss of control of uveitis, active uveitis, and complications can lead to partial or permanent vision loss.
§ These are not reversible changes and should not be indications to change treatment in the absence of active inflammation.

patients with JIA, assisted with developing the scope of the project and refining PICO questions, reviewed the collated evidence, and voted on the recommendations; and 5) a Parent and Patient Panel, consisting of 9 adult patients with JIA and 2 parents of children with JIA and uveitis, reviewed the collated evidence and provided input on their values and preferences, within the context of a separate voting meeting. Supplementary Appendix 2 (available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23871/abstract) presents rosters of the team and panel members. In accordance with ACR policy, the principal investigator and the leader of the Literature Review Team were free of potential conflicts of interest, and in all teams, >50% of the members were free of potential conflicts of interest.

PICO question development and importance of outcomes. The Core Leadership Team drafted the initial project scope, key principles, and relevant clinical PICO questions. These were then presented to the guideline development groups for their review at a scoping face-to-face meeting in which the project plan was defined. GRADE criteria provided the framework for judging the overall quality of evidence (13).

During the scoping meeting, the guideline scope, key terms, and definitions were discussed and agreed upon (Table 1). The Expert Panel chose the following 3 areas of focus: 1) ophthalmic screening for uveitis in children with JIA, 2) ophthalmic monitoring of established uveitis in children with JIA, and 3) use of topical and systemic glucocorticoids and systemic immunosuppressant medications to treat uveitis. This guideline pertains to children with JIA and either CAU or AAU. The Expert Panel defined "controlled uveitis" as an inactive OR grade of <1+ anterior chamber (AC) cells without new complications due to active inflammation per Standardization of Uveitis Nomenclature (SUN) criteria (16). "Loss of control" of uveitis was defined as an increase of AC cells to grade 1+ or more or new signs of inflammation/complications of inflammation. A grade of 1+ AC cells is 6–15 cells/field in a 1-mm × 1-mm slit beam, as seen through a biomicroscope. The term "new uveitis activity" included either new activity in patients with no history of uveitis or recurrent activity in patients with loss of control of previously controlled uveitis. Complications due to active inflammation, additional signs of active inflammation, and complications representing cumulative damage were also defined (Table 1). Loss of control of uveitis, active uveitis, and complications can lead to partial or permanent vision loss.

Critical and important outcomes varied based on the type of recommendation (Table 2). Critical outcomes related to screening included new diagnosis of uveitis and new diagnosis of uveitis with any ocular complications (Table 2). Critical outcomes related to monitoring included loss of control of uveitis and new complications due to inflammation. Critical outcomes related to medication use included loss of control of uveitis, incidence of loss of control of uveitis (rate or frequency of loss of control of uveitis, i.e., number of episodes over time), control of uveitis at 1 month and 3 months, new glucocorticoid-related ocular complications (cataracts, glaucoma/increased intraocular pressure [IOP], infection), and new ocular complications due to inflammation, incident uveitis, and recurrence of uveitis. Other important outcomes for monitoring were severity and level of inflammation and for medication use were side effects of systemic therapy, time to control of uveitis, and time to loss of control of uveitis.

Table 2. Critical and important outcomes*

Type of recommendation	Outcome
Screening	
Critical outcomes	New diagnosis of uveitis
	New diagnosis of uveitis with ANY ocular complications
Monitoring	
Critical outcomes	Loss of control of uveitis
	New complications due to inflammation
Important outcomes	Severity/level of inflammation
Treatment	
Critical outcomes	Loss of control of uveitis
	Incidence of loss of control of uveitis
	Control of uveitis at 1 month and 3 months
	New ocular glucocorticoid complications (cataracts, glaucoma/increased intraocular pressure, infection)
	New ocular complications due to inflammation
	Incident uveitis
	Recurrence of uveitis
Important outcomes	Side effects of systemic therapy
	Time to control of uveitis
	Time to loss of control of uveitis

* Vary depending on the recommendation.

Synthesis of the literature and grading of the evidence. Systematic searches of the published English language literature included OVID Medline, PubMed, Embase, and the Cochrane Library (including Cochrane Database of Systematic Reviews, Database of Abstracts of Reviews of Effects, Cochrane Central Register of Controlled Trials, and Health Technology Assessments) from inception through June 12, 2017 (see Supplementary Appendix 3, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23871/abstract); updated searches were conducted on October 13, 2017. DistillerSR software (https://dis-

tillercer.com/products/distillersr-systematic-reviewsoftware/) (Supplementary Appendix 4, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23871/abstract) facilitated duplicate screening of literature search results. Reviewers entered extracted data into RevMan software (http://tech.cochrane.org/revman) and evaluated the risk of bias of primary studies using the Cochrane risk of bias tool (http://handbook.cochrane.org/). RevMan files were exported into GRADEpro software to formulate a GRADE summary of a table showing the GRADE summary of findings (see Supplementary Appendix 5, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23871/abstract) for each PICO question (17).

When data were available, the evidence summaries included the benefits and harms for outcomes of interest across studies, the relative effect (with effect size and 95% confidence interval), the number of participants, and the absolute effects. We rated the quality of evidence (also called certainty) for each critical and important outcome as high, moderate, low, or very low quality, taking into account risk of bias, inconsistency, indirectness, imprecision, and other considerations as per the GRADE recommendations.

Moving from evidence to recommendations. GRADE methodology specifies that panels make recommendations based on the balance of benefits and harms, the quality of the evidence (i.e., confidence in effect estimates), and parents/patients' values and preferences. Deciding on the balance between desirable and undesirable outcomes requires estimating the relative value patients place on those outcomes. When the literature did not provide clear evidence, recommendations were based on the values/preferences input from the members of the Parent and Patient Panel and on the experience of the Voting Panel members (including physicians and the 2 patients present).

Consensus building. The Voting Panel voted on the direction and strength of the recommendation related to each PICO question. Recommendations required a 70% level of agreement; if 70% agreement was not achieved during an initial vote, Voting Panel members held additional discussions before re-voting, including rewording of recommendations if needed, until consensus was attained (18). For all conditional recommendations, a written explanation is provided, describing the reasons for this decision and conditions under which the alternative may be preferable. A second round of voting occurred after the face-to-face meeting for recommendations with additional questions. In some instances, the Voting Panel combined PICO questions into 1 recommendation for clarity. Some PICO questions were dropped during the consensus meeting due to insufficient evidence to make a formal recommendation (see Supplementary Appendix 6, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23871/abstract).

Moving from recommendations to practice. These recommendations are designed to help health care providers work with parents/patients in selecting therapies. Health care providers and parents/patients must take into consideration all active disease domains, comorbidities, and the patient's functional status when choosing the optimal therapy for an individual patient.

RESULTS/RECOMMENDATIONS

The literature searches retrieved 1,704 initial citations, 131 duplications were removed, and 1,537 unique uveitis citations were identified. Full-length articles were abstracted and graded for evidence related to the 34 PICO questions. The available evidence was very low-quality for all PICO questions, mainly because of the lack of evidence and the indirectness of the evidence. Most articles were based on observational studies, which are considered to be low-quality in the GRADE system.

How to interpret the recommendations

1. A *strong recommendation* means that the Voting Panel was confident that the desirable effects of following the recommendation outweigh the undesirable effects (or vice versa), so the course of action would apply to all or almost all patients, and only a small proportion would not want to follow the recommendation. Due to the risk of ocular complication with resultant vision loss with irregular or infrequent monitoring, and because ophthalmic examinations are low-risk, all recommendations on ophthalmic monitoring examinations of children with uveitis were strong despite the very low quality of evidence. Patients were concerned about the consequences of infrequent monitoring and agreed there was little disadvantage to monitoring, including the potential cost and inconvenience of frequent visits.
2. A *conditional recommendation* means the Voting Panel believed that the desirable effects of following the recommendation probably outweigh the undesirable effects, so the course of action would apply to the majority of the patients, but some may not want to follow the recommendation. Because of patient preference and lack of strong evidence, conditional recommendations are preference-sensitive and always warrant a shared decision-making approach. All of the treatment recommendations were conditional, except for 1 related to tapering topical glucocorticoids (Recommendation 18).
3. All of the recommendations had a very low quality of evidence; thus, most of the recommendations are conditional.
4. All of the recommendations are meant to apply to children with JIA at risk of and with associated uveitis, *regardless of activity of arthritis and other manifestations of JIA*.
5. When deciding on the frequency of ophthalmic monitoring and treatment, close collaboration and communication be-

Table 3. Recommendations for ophthalmic screening, ophthalmic monitoring, and treatment of children with JIA-associated uveitis*

Recommendation
Recommendations for ophthalmic screening
In children and adolescents with JIA at high risk of developing uveitis:†
• Ophthalmic screening every 3 months is conditionally recommended (Recommendation 1, PICO 1).
Recommendations for ophthalmic monitoring
In children and adolescents with JIA and controlled uveitis who are:
• Tapering or discontinuing topical glucocorticoids, ophthalmic monitoring within 1 month after each change of topical glucocorticoids is ***strongly*** recommended over monitoring less frequently (Recommendation 2, PICO 3). • On stable therapy, ophthalmic monitoring no less frequently than every 3 months is ***strongly*** recommended over monitoring less frequently (Recommendation 3, PICO 2). • Tapering or discontinuing systemic therapy, ophthalmic monitoring within 2 months of changing systemic therapy is ***strongly*** recommended over monitoring less frequently (Recommendation 4, PICO 4).
Recommendations for glucocorticoid use
In children and adolescents with JIA and active CAU:
• Using prednisolone acetate 1% topical drops is conditionally recommended over difluprednate topical drops (Recommendation 5, PICO 10). • Adding or increasing topical glucocorticoids for short-term control is conditionally recommended over adding systemic glucocorticoids (Recommendation 6, PICO 11).
In children and adolescents with JIA and CAU still requiring 1–2 drops/day of prednisolone acetate 1% (or equivalent) for uveitis control:
• If not on systemic therapy, adding systemic therapy in order to taper topical glucocorticoids is conditionally recommended over not adding systemic therapy and maintaining topical glucocorticoids only (Recommendation 8, PICO 7). • If still requiring 1–2 drops/day of prednisolone acetate 1% (or equivalent) for at least 3 months and on systemic therapy, changing or escalating systemic therapy is conditionally recommended over maintaining current systemic therapy (Recommendation 9, PICO 8).
In children and adolescents with JIA who develop new CAU activity despite stable systemic therapy:‡
• Topical glucocorticoids prior to changing/escalating systemic therapy is conditionally recommended over changing/escalating systemic therapy immediately (Recommendation 7, PICO 12).
Recommendations for DMARDs and biologics
In children and adolescents with JIA and active CAU who are/have:
• Starting systemic treatment for uveitis, using subcutaneous methotrexate is conditionally recommended over oral methotrexate (Recommendation 10, PICO 13). • Starting a TNFi, starting a monoclonal antibody TNFi is conditionally recommended over etanercept (Recommendation 12, PICO 15). • Severe active CAU and sight-threatening complications, starting methotrexate and a monoclonal antibody TNFi immediately is conditionally recommended over methotrexate as monotherapy (Recommendation 11, PICO 22). • Inadequate response to one monoclonal TNFi at standard JIA dose, escalating the dose and/or frequency of the monoclonal TNFi to above standard is conditionally recommended over switching to another monoclonal antibody TNFi (Recommendation 13, PICO 20). • Failed a first monoclonal antibody TNFi at above-standard dose and/or frequency, changing to another monoclonal antibody TNFi is conditionally recommended over a biologic in another category (Recommendation 14, PICO 21). • Failed methotrexate and 2 monoclonal antibody TNFi at above-standard dose and/or frequency, abatacept or tocilizumab are conditionally recommended as biologic DMARD options, and mycophenolate, leflunomide, or cyclosporine as alternative nonbiologic options (Recommendation 15, PICO 23).
Recommendations for education about and treatment of AAU
In children and adolescents with spondyloarthritis:
• ***Strongly*** recommend education regarding the warning signs of AAU for the purpose of decreasing delay in treatment, duration of symptoms, or complications of iritis (Recommendation 16, PICO 32). • Well controlled with systemic immunosuppressive therapy (DMARD, biologics) who develop an isolated short-lived episode of AAU, conditionally recommend against switching systemic immunosuppressive therapy immediately in favor of treating with topical glucocorticoids first (Recommendation 17, PICO 34).

(continued)

Table 3. (*Cont'd*)

Recommendation
Recommendations for tapering therapy for uveitis
In children and adolescents with JIA and CAU that is controlled on systemic therapy but remain on 1–2 drops/day of prednisolone acetate 1% (or equivalent):
• Tapering topical glucocorticoids first is ***strongly*** recommended over systemic therapy (Recommendation 18, PICO 6).
In children and adolescents with JIA and uveitis that is well controlled on DMARD and biologic systemic therapy only:
• Conditionally recommend that there be at least 2 years of well-controlled disease before tapering therapy (Recommendation 19, PICO 29).

* Each recommendation had very low quality level of evidence. JIA = juvenile idiopathic arthritis; PICO = Patient/Population, Intervention, Comparison, and Outcomes; CAU = chronic anterior uveitis; DMARDs = disease-modifying antirheumatic drugs; TNFi = tumor necrosis factor inhibitor; AAU = acute anterior uveitis.
† High-risk children are those with oligoarthritis, polyarthritis (rheumatoid factor negative), psoriatic arthritis, or undifferentiated arthritis who are also antinuclear antibody positive, younger than 7 years of age at JIA onset, and have JIA duration of 4 years or less.
‡ Definition of new CAU activity: no prior uveitis or loss of control of previously controlled uveitis.

tween rheumatology and ophthalmology subspecialists is crucial. Points to consider include degree of ocular inflammation, presence of complications, use of topical glucocorticoids, and level of IOP.

6. Recommendations on topical glucocorticoids pertain to prednisolone acetate 1% or equivalent dosing with other types of topical glucocorticoids.
7. Recommendations on systemic therapy pertain to nonbiologic DMARDs and biologics and not systemic glucocorticoids.
8. Recommendations that consider TNFi biologics pertain to etanercept, adalimumab, and infliximab only. Monoclonal antibody TNFi refers to adalimumab and infliximab, due to lack of data and experience with other agents (golimumab, certolizumab, or biosimilars) for uveitis in pediatric patients. Only adalimumab, infliximab, etanercept, abatacept, and tocilizumab were discussed, because data on the use of other biologics for treatment of uveitis are lacking.

Recommendation for ophthalmic screening of children with JIA (Table 3 and Figure 1A)

Recommendation 1. *In children and adolescents with JIA at high risk of developing uveitis, ophthalmic screening every 3 months is conditionally recommended over screening at a different frequency.*

The Voting Panel agreed with combining the screening recommendations of the AAP Sections on Rheumatology and Ophthalmology and the German Uveitis in Childhood Study Group (German recommendations) (8,9). AAP recommendations are based on the older classification scheme "juvenile rheumatoid arthritis," which does not include ILAR categories of psoriatic JIA, enthesitis-related arthritis, and undifferentiated arthritis. The screening schedule suggested by the German recommendations incorporates these categories and recommends screening high-risk children every 3 months, similar to the AAP recommendations. Based on the combined AAP and German recommendations, high-risk children are those with oligoarthritis, polyarthritis (rheumatoid factor negative), psoriatic arthritis, or undifferentiated arthritis who are also antinuclear antibody (ANA) positive, younger than 7 years of age at JIA onset, and have JIA duration of 4 years or less. Low- or moderate-risk children are those with high-risk JIA categories but who are ANA negative, age 7 years or older at JIA onset, or have JIA duration of more than 4 years, and those with systemic JIA, polyarthritis (rheumatoid factor positive), and enthesitis-related arthritis. Low- or moderate-risk children should be screened every 6–12 months depending on their combination of risk factors. Because children who have enthesitis-related arthritis or are carrying the HLA–B27 genotype are at risk of both AAU and CAU, they require screening as well. This recommendation was conditional, based on the low quality of evidence, although several reports have described factors that increase the risk of developing uveitis (19–24). Some children have significant eye disease at the time of screening under the current schedule, but there is a lack of data showing that more frequent screening is beneficial. Patients and parents supported the recommended frequency of screening and expressed a desire for frequent screening.

Recommendations for ophthalmic monitoring of children with JIA diagnosed with uveitis (Table 3 and Figure 1B)

Recommendation 2. *In children and adolescents with JIA and controlled uveitis who are tapering or discontinuing topical glucocorticoids, ophthalmic monitoring within 1 month after each change of topical glucocorticoids is* ***strongly*** *recommended over monitoring less frequently.*

Recommendation 3. *In children and adolescents with JIA and controlled uveitis on stable therapy, ophthalmic monitoring*

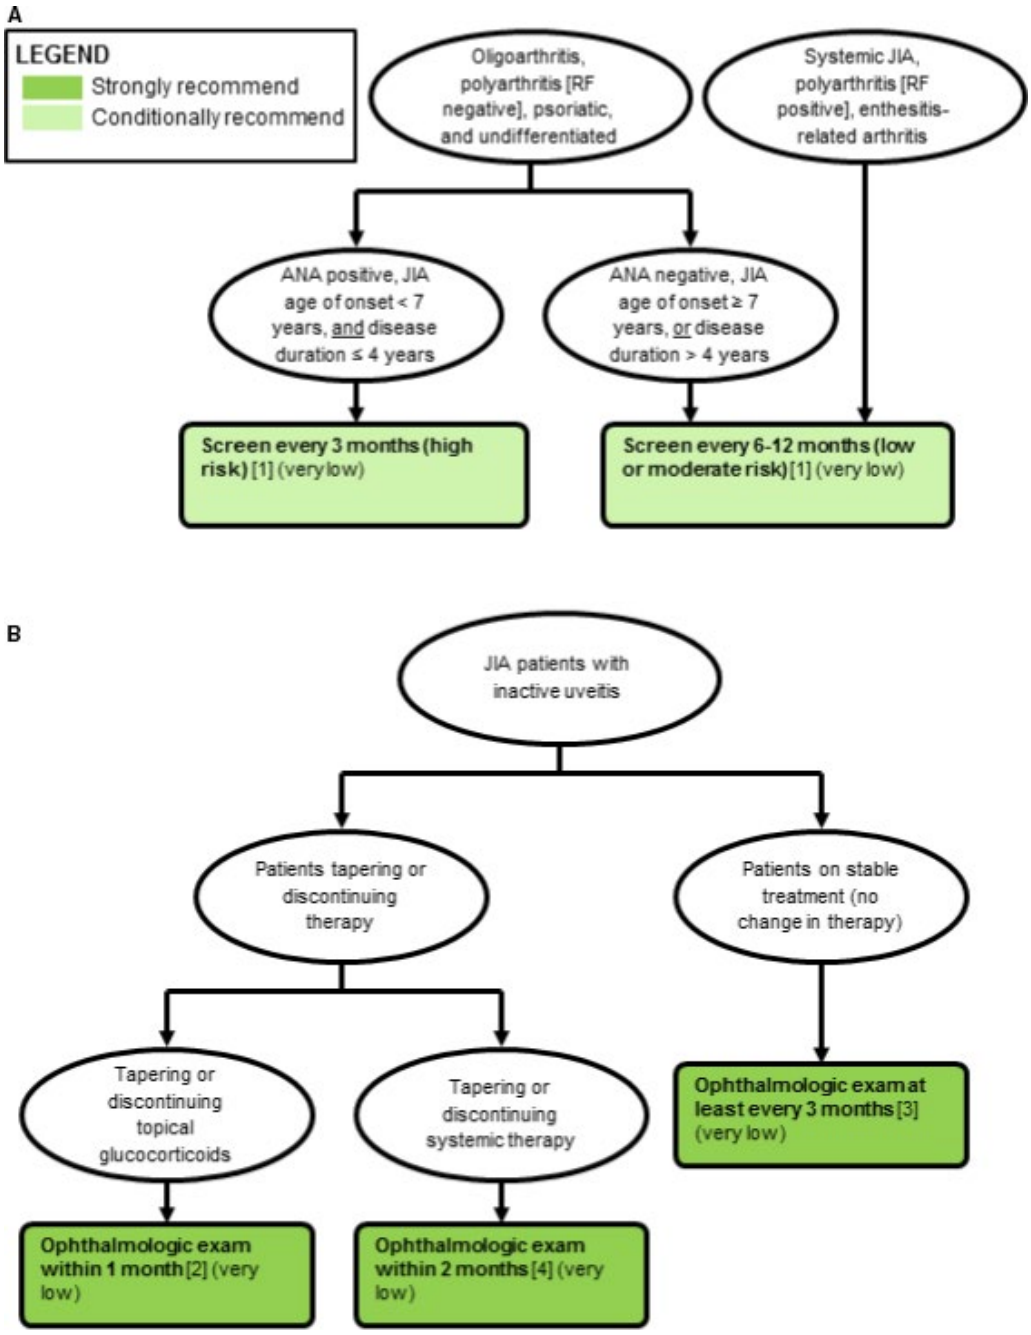

Figure 1. **A,** Ophthalmic screening examinations (see also Table 1). **B,** Ophthalmic monitoring examinations (see also Table 3). No recommendations were made for patients with uncontrolled chronic anterior uveitis. Patient/Population, Intervention, Comparison, and Outcomes (PICO) questions are shown in brackets, and quality of evidence is shown in parentheses. JIA = juvenile idiopathic arthritis; RF = rheumatoid factor; ANA = antinuclear antibody.

no less frequently than every 3 months is ***strongly*** *recommended over monitoring less frequently.*

Recommendation 4. *In children and adolescents with JIA and controlled uveitis who are tapering or discontinuing systemic therapy, ophthalmic monitoring within 2 months of changing systemic therapy is* ***strongly*** *recommended over monitoring less frequently.*

The need for regular monitoring of children with established uveitis was emphasized. The Voting Panel recommends that children with controlled CAU on stable medication should be monitored at 3-month intervals, and those tapering or discontinuing therapy should be monitored at intervals shorter than 3 months, either within 1 month after each change in topical glucocorticoids, and within 2 months of a change in systemic therapy (Figure 1B). Although the quality of evidence was very

low, the recommendations for monitoring were strong due to the potential for harmful consequences of irregular or infrequent monitoring of children with CAU, which could lead to substantial loss of vision and ocular complications from undetected exacerbation of inflammation (20,25). Patients were generally concerned about the consequences of infrequent monitoring and agreed that there was little disadvantage to having frequent ophthalmic examinations. The Voting Panel agreed that the frequency of monitoring may be influenced by the half-life of the systemic therapy and by the expected time for efficacy.

The Voting Panel was not able to reach consensus on a standard schedule of ophthalmic monitoring in children and adolescents with *uncontrolled* CAU; thus, no formal recommendation was made. The Voting Panel agreed, however, that regular monitoring is needed for uncontrolled uveitis, and that in most cases, examinations could occur at 2–6-week intervals tailored to the frequency of topical glucocorticoid administration, IOP, degree of inflammation, and presence of complications, as agreed on by the treatment team.

Recommendations for glucocorticoid use (Table 3 and Figure 2)

Recommendation 5. *In children and adolescents with JIA and active CAU, using prednisolone acetate 1% topical drops is conditionally recommended over difluprednate topical drops.*

Recommendation 6. *In children and adolescents with JIA and active CAU, adding or increasing topical glucocorticoids for short-term control is conditionally recommended over adding systemic glucocorticoids.*

Frequent administration of topical glucocorticoids should be used as initial therapy to control inflammation, followed by tapering as soon as the AC cellular reaction comes under control. The recommendation was conditional based on the very low quality of evidence (26). Prednisolone acetate 1% topical drops are the preferred topical glucocorticoid based on better corneal penetration compared with other eye drops and the fact that there is less experience with difluprednate, which has an increased risk of glucocorticoid-induced IOP and cataract formation (27,28). However, because long-term comparison data between both formulations are lacking, this recommendation was conditional. Patient compliance should be taken into consideration, because prednisolone acetate 1% requires more frequent administration due to its lower potency compared with difluprednate. The Voting Panel recognized that in selected patients, systemic glucocorticoids can be used as short-term bridging therapy. The Voting Panel did not seek consensus to make a recommendation on the use of periocular or intraocular glucocorticoids.

Recommendation 7. *In children and adolescents with JIA who develop new CAU activity despite stable systemic therapy, topical glucocorticoids prior to changing/escalating systemic therapy is conditionally recommended over changing/escalating systemic therapy immediately.*

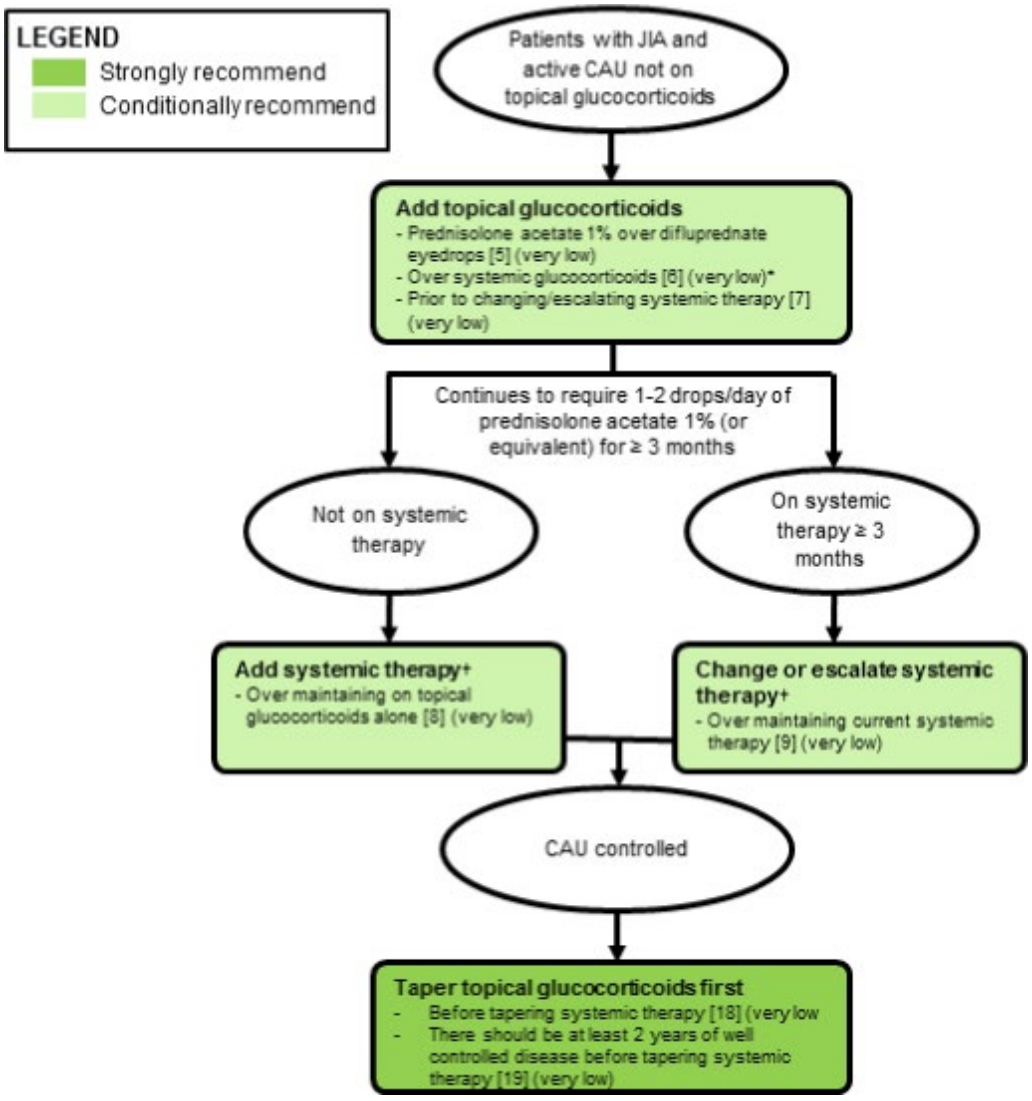
Initially, topical glucocorticoids should be given to children with uncontrolled uveitis, whether there is a new diagnosis or exacerbation of previously controlled uveitis, unless there is a contraindication. Adding, changing, or escalating (increasing the dose or frequency) systemic therapy should be considered in those children who continue to require prednisolone acetate 1% 1–2 drops/day (or equivalent) (Recommendations 8 and 9). This recommendation was conditional based on very low quality of data.

Recommendation 8. *In children and adolescents with JIA and CAU still requiring 1–2 drops/day of prednisolone acetate 1% (or equivalent) for uveitis control, and not on systemic therapy, adding systemic therapy in order to taper topical glucocorticoids is conditionally recommended over not adding systemic therapy and maintaining on topical glucocorticoids only.*

The risk of elevated IOP and cataracts increases with greater frequency of administration of topical glucocorticoids (drops/day) and longer duration of therapy. Kothari et al found that topical glucocorticoids at a dosage of ≥2 drops/day was a strong risk factor for IOP elevation, which increased with a greater number of drops daily (29). Another retrospective cohort study showed that ≤3 drops/day of prednisolone is preferred to ≥4 drops/day to decrease the risk of developing cataracts (30). The Voting Panel recommends adding systemic DMARD therapy in children needing ongoing topical glucocorticoids to control uveitis, with the ultimate goal of discontinuation of topical glucocorticoids. These recommendations were conditional due to very low quality of data, and because there may be reasons why a dosage of 1–2 drops/day of topical prednisolone is unacceptable, such as the presence of complications from use of topical glucocorticoids, contraindications to topical glucocorticoids, and difficulty in compliance with multiple drops per day. Nevertheless, prednisolone at a dosage of 1–2 drops/day may be appropriate as monotherapy if there are no issues with ocular complications such as elevated IOP and cataracts, no difficulties with the use of topical glucocorticoids, and there is regular close follow-up with an ophthalmologist.

Recommendation 9. *In children and adolescents with JIA and CAU still requiring 1–2 drops/day of prednisolone acetate 1% (or equivalent) for at least 3 months and on systemic therapy for uveitis control, changing or escalating systemic therapy is conditionally recommended over maintaining current systemic therapy.*

The Voting Panel agreed on 3 months as the threshold for adding or changing systemic therapy in children who require topical glucocorticoids to maintain uveitis control. Nevertheless, changes in systemic therapy may be warranted earlier, depending on findings on the ocular examination, the duration of topical and systemic therapy, and the presence of existing complications. The recommendation was conditional because of the very low quality of the



LEGEND
Strongly recommend
Conditionally recommend
Patients with JIA and active CAU not on topical glucocorticoids
Add topical glucocorticoids
- Prednisolone acetate 1% over difluprednate eyedrops [5] (very low)
- Over systemic glucocorticoids [6] (very low)*
- Prior to changing/escalating systemic therapy [7] (very low)
Continues to require 1-2 drops/day of prednisolone acetate 1% (or equivalent) for ≥ 3 months
Not on systemic therapy
On systemic therapy ≥ 3 months
Add systemic therapy+
- Over maintaining on topical glucocorticoids alone [8] (very low)
Change or escalate systemic therapy+
- Over maintaining current systemic therapy [9] (very low)
CAU controlled
Taper topical glucocorticoids first
- Before tapering systemic therapy [18] (very low
- There should be at least 2 years of well controlled disease before tapering systemic therapy [19] (very low)

Figure 2. Recommendations for topical glucocorticoids in patients with juvenile idiopathic arthritis (JIA) and chronic anterior uveitis (CAU) (see also Table 3). Systemic therapy is defined as disease-modifying antirheumatic drugs and biologics. Topical glucocorticoids refer to prednisolone acetate 1% (or equivalent). Doses of prednisolone acetate 1% greater than 1–2 drops/eye/day may be needed initially but increase the risk of ocular complications. Topical glucocorticoids should be used as short-term therapy (≤3 months). The goal is to discontinue topical glucocorticoid use, due to risk of glaucoma and cataracts. Periocular and intraocular injections are administered at the discretion of the treating ophthalmologist. The recommendation numbers are shown in brackets, and quality of evidence is shown in parentheses. * = In selected patients, systemic glucocorticoids can be used as short-term bridging therapy. † = Can escalate dose or frequency of current therapy; 3 months is the threshold for adding or changing systemic therapy in children who require topical glucocorticoids to maintain uveitis control. Changes in systemic therapy may be warranted earlier, depending on findings on the ocular examination, the duration of topical and systemic therapy, and the presence of existing complications.

evidence, the variation in the severity of a child's disease presentation, child and family preference for topical medication over systemic therapy, and the specific systemic therapy being considered.

Recommendations for DMARDS and biologics (Table 3)

Recommendation 10. *In children and adolescents with JIA and CAU who are starting systemic treatment for uveitis, using subcutaneous methotrexate is conditionally recommended over oral methotrexate.*

Recommendation 11. *In children and adolescents with JIA with severe active CAU and sight-threating complications, starting methotrexate and a monoclonal antibody TNFi immediately is conditionally recommended over methotrexate as monotherapy.*

Methotrexate and monoclonal antibody TNFi are the mainstays of systemic treatment of uveitis. Subcutaneous

methotrexate was considered preferable to oral administration for uveitis, but this recommendation was conditional given the lack of strong data on differential efficacy and the notion that family preferences regarding the route of administration may differ. In children with severe active uveitis and sight-threatening complications, combining methotrexate with a monoclonal antibody TNFi at the time of initiation of systemic immunosuppressive treatment was recommended over methotrexate as monotherapy. Severe uveitis could be considered as the presence of ocular structural complications due to uveitis or complications of topical steroid therapy (31). This recommendation was conditional based on the lack of direct evidence from studies, the risk of permanent vision loss, and anticipated differences in patient values and preferences.

Recommendation 12. *In children and adolescents with JIA and active CAU starting a TNFi, starting a monoclonal antibody TNFi is conditionally recommended over etanercept.*

Monoclonal antibody TNFi, specifically adalimumab and infliximab, were conditionally recommended over etanercept for active CAU. Although there is a paucity of direct comparisons, a benefit of using monoclonal antibody TNFi has been shown. The Voting Panel was not able to make recommendations on the preferred TNFi treatment for children with active JIA to prevent uveitis onset or for children with known CAU to prevent uveitis flares, due to lack of evidence (32–36). The Voting Panel also did not make a recommendation on preference between adalimumab and infliximab for use as the initial TNFi.

Recommendation 13. *In children and adolescents with JIA and active CAU who have an inadequate response to 1 monoclonal antibody TNFi at standard JIA dose, escalating the dose and/or frequency to above standard is conditionally recommended over switching to another monoclonal antibody TNFi.*

Recommendation 14. *In children and adolescents with JIA and active CAU who have failed a first monoclonal antibody TNFi at above-standard dose and/or frequency, changing to another monoclonal antibody TNFi is conditionally recommended over a biologic in another category.*

Recommendations 13 and 14 assume that uveitis activity or severity guides therapy in the patient, irrespective of joint disease activity. The Voting Panel did not make a recommendation regarding preference between adalimumab and infliximab as a first-line TNFi or use of above-standard TNFi dosing at treatment initiation.

For children treated with a monoclonal antibody TNFi at standard dosing for patients with JIA who have an inadequate response to therapy, the Voting Panel conditionally recommended escalating the dose and/or frequency to above-standard dosing used for arthritis prior to switching to another monoclonal antibody TNFi. Although consensus was not reached regarding a specific dose or frequency, doses as high as infliximab 20 mg/kg administered every 2 weeks and adalimumab weekly have been reported in observational studies in children with JIA and uveitis (37–39). If treatment with an increased dose/frequency of the initial monoclonal antibody TNFi fails, the recommendation was to change to another monoclonal antibody TNFi prior to changing to a biologic agent in another category. These recommendations were conditional due to the very low quality evidence.

Recommendation 15. *In children and adolescents with JIA and active CAU who have failed methotrexate and 2 monoclonal antibody TNFi at above-standard dose and/or frequency, the use of abatacept or tocilizumab as biologic DMARD options, and mycophenolate, leflunomide, or cyclosporine as alternative nonbiologic DMARD options is conditionally recommended.*

The quality of evidence for subsequent treatment in children who have failed methotrexate in combination with monoclonal antibody TNFi treatment is very low. Based on the current literature, recommended alternative nonbiologic options are mycophenolate mofetil (40), leflunomide (41), or cyclosporine (42), and recommended alternative biologic options are abatacept (43–45) or tocilizumab (46,47); however, evidence supporting preference for a specific nonbiologic or biologic DMARD, combination therapies, and timing of initiation beyond methotrexate, adalimumab, and infliximab is currently lacking. For clarity, several PICO questions were combined in this recommendation.

Recommendations for education about and treatment of acute anterior uveitis (Table 3)

Recommendation 16. *In children and adolescents with spondyloarthritis,* ***strongly*** *recommend education regarding the warning signs of AAU for the purpose of decreasing delay in treatment, duration of symptoms, or complications of iritis.*

AAU is generally a manifestation in a subset of children who are HLA–B27 positive with enthesitis-related arthritis and in some cases of psoriatic arthritis. Although the quality of evidence was very low (no studies addressing these topics were identified), the Voting Panel strongly agreed, based on experience, that HLA–B27–positive patients with enthesitis-related arthritis or psoriatic arthritis and their families should be educated regarding warning signs of AAU, for the purpose of decreasing delay in treatment, duration of symptoms, or ocular complications. Signs include eye pain, redness, and photophobia. This recommendation was strong, because educating about a disease and warning signs is the standard of care.

Recommendation 17. *In children and adolescents with spondyloarthritis otherwise well controlled with systemic immunosuppressive therapy (DMARDs, biologics) who develop AAU, conditionally recommend against switching systemic immunosuppressive*

therapy immediately in favor of treating with topical glucocorticoids first.

Because AAU episodes are typically of short duration and may be easily controlled with topical glucocorticoids, the Voting Panel conditionally recommended continuing the same systemic immunosuppressive therapy and treating with topical glucocorticoids at the initial development of AAU (48). During an isolated short-lived episode of AAU, an immediate escalation or change in underlying systemic therapy may not be necessary without trying a course of topical glucocorticoids first. This recommendation was conditional, because there is a lack of supporting data. Furthermore, frequent recurrent episodes of AAU may prompt a change from a non–monoclonal antibody TNFi to a monoclonal antibody TNFi, or there may be ocular complications from use of topical glucocorticoids that require prompt adjustment of systemic treatment, to decrease exposure to glucocorticoid therapy.

Recommendations for tapering therapy for uveitis (Table 3)

Recommendation 18. *In children and adolescents with JIA and CAU that is controlled on systemic therapy but who remain on 1–2 drops/day of prednisolone acetate 1% (or equivalent), tapering topical glucocorticoids first is* ***strongly*** *recommended over systemic therapy.*

There is very low quality of evidence for timing of tapering of topical glucocorticoids and systemic therapy (25,49,50). Some ophthalmologists feel that in selected cases, it is not possible to discontinue topical glucocorticoids altogether, despite attempts to do so, and the patients may continue to receive 1–2 drops/day for extended periods of time. Despite the very low quality of evidence, the Voting Panel strongly recommended attempting to taper topical glucocorticoids prior to tapering systemic therapy because of the secondary complications that can occur with prolonged and frequent use of glucocorticoids (29,30). Tapering of systemic therapy first may lead to the need for increased frequency of topical glucocorticoids for uveitis flares.

Recommendation 19. *In children and adolescents with uveitis that is well controlled on DMARD and biologic systemic therapy only, conditionally recommend that there be at least 2 years of well-controlled disease before tapering therapy.*

The Voting Panel conditionally recommends attempted tapering of DMARD and biologic systemic therapy only after uveitis has been well controlled for at least 2 years. Relapse-free survival after withdrawal of methotrexate was significantly longer in patients treated with methotrexate for more than 3 years and who had controlled uveitis for more than 2 years before the withdrawal (50). Duration of systemic therapy may be longer than 2 years, because tapering should not begin until at least 2 years of uveitis control. Decisions to taper systemic therapy should also take into consideration other JIA manifestations, including arthritis activity.

DISCUSSION

This 2019 ACR guideline provides direction on the screening of children with JIA at risk of CAU, monitoring of children diagnosed with CAU, treatment with glucocorticoids, nonbiologic DMARDs, and biologic DMARDs for CAU, and education and treatment of children with or at risk of AAU. Few uveitis practice guidelines have a scope this broad (51–54). Although the quality of evidence was very low, and most recommendations were therefore conditional, this guideline fills an important clinical gap in the care of children with JIA-associated uveitis and may be updated as better evidence becomes available.

Optimal care of children with uveitis requires careful and close collaboration among subspecialists, because, in most cases, ophthalmologists assess uveitis activity and ocular complications and provide topical therapy, and rheumatologists manage systemic treatment. Thus, the Voting Panel consisted of both pediatric rheumatologists and ophthalmologists with expertise in uveitis evaluation and management. We acknowledge that there were more pediatric rheumatologists than ophthalmologists on the Voting Panel. However, both ophthalmologists were active in the voting process and in all discussions that led to the final recommendations.

A major limitation is the lack of good-quality evidence in children with JIA and uveitis. Only 1 well-conducted RCT on the use of adalimumab and methotrexate in children with JIA-associated uveitis was identified (11). This highlights the necessity for further studies in this population. We limited our recommendations to biologic DMARDs for which there were sufficient observational data and experience. Thus, biologics such as rituximab, golimumab, certolizumab, TNFi biosimilars, and the nonbiologic drug tofacitinib were not considered. These agents may be included in future guidelines. Although we based our recommendations on studies that focused on the treatment of uveitis specifically, it is difficult to separate treatment of arthritis and CAU in studies. Also, cost was not formally taken into consideration in the guideline. There was heavy reliance on 1 high-quality RCT for the guideline (11), and due to the lack of controlled trial data, most recommendations relied on expert opinion. There is an urgent need for RCTs in children with JIA-associated uveitis, which will better inform treatment decisions in this population. In addition, further investigations are needed on the role of antidrug antibodies, long-term ophthalmic screening in children with JIA, and drug tapering in children with refractory uveitis. As more evidence becomes available, these can inform future guidelines.

In summary, these recommendations provide guidance on the evaluation and management of children at risk of and those with JIA-associated uveitis by rheumatology and ophthalmology

experts, current literature, and patient and parent preferences and values, using state-of-the-art GRADE methodology. Persistent uncontrolled uveitis leads to sight-threatening ocular complications and permanent vision loss. The ultimate goal is to maintain optimal vision and ocular health in children with uveitis by limiting the duration of ocular inflammation, minimizing exposure to long-term topical glucocorticoids through the expedited use of systemic medications, and preventing secondary ocular sequelae.

SPECIAL ARTICLE

2013 Update of the 2011 American College of Rheumatology Recommendations for the Treatment of Juvenile Idiopathic Arthritis

Recommendations for the Medical Therapy of Children With Systemic Juvenile Idiopathic Arthritis and Tuberculosis Screening Among Children Receiving Biologic Medications

Sarah Ringold,[1] Pamela F. Weiss,[2] Timothy Beukelman,[3] Esi Morgan DeWitt,[4] Norman T. Ilowite,[5] Yukiko Kimura,[6] Ronald M. Laxer,[7] Daniel J. Lovell,[4] Peter A. Nigrovic,[8] Angela Byun Robinson,[9] and Richard K. Vehe[10]

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for particular patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to these guidelines and recommendations to be voluntary, with the ultimate determination regarding their application to be made by the physician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed or endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice.

The American College of Rheumatology is an independent, professional, medical and scientific society which does not guarantee, warrant, or endorse any commercial product or service.

INTRODUCTION

The American College of Rheumatology (ACR) published treatment recommendations for juvenile idiopathic arthritis (JIA) in 2011 (1). These recommendations represented the first such effort by the ACR that focused entirely on the treatment of a pediatric rheumatic disease, and included recommendations for the initial and subsequent treatment of patients with synovitis and systemic manifestations and recommendations

This article is published simultaneously in the October 2013 issue of *Arthritis Care & Research*.

for medication safety monitoring. Also included in the recommendations was a statement regarding potential areas for a subsequent update. Based on the progress made understanding the pathophysiology of systemic JIA and a rapid increase in data regarding the treatment of systemic JIA and how it differs from other categories of JIA, the ACR determined that the treatment of systemic JIA should be the focus of the first update.

Systemic JIA accounts for approximately 4–15% of JIA and is defined as arthritis in ≥1 joint for at least 6 weeks' duration in a child age <16 years with or preceded by fever of at least 2 weeks' duration that is documented to be daily ("quotidian") for at least 3 days and accompanied by one or more of the following: evanescent erythematous rash, generalized lymphadenopathy, hepatomegaly or splenomegaly, and serositis (2). The goal of therapy for systemic JIA is similar to that of the other categories of JIA, and focuses on the prompt control of active inflammation and symptoms and the prevention of a number of disease- and/or treatment-related morbidities such as growth disturbances, joint damage, and functional limitations. Many children with systemic JIA have a particularly refractory course, with persistent disease associated with a high risk of joint damage and severe growth impairment (3–5). However, the inflammatory process underlying systemic JIA appears to be distinct from other categories of JIA, with a central role for both interleukin-1 (IL-1) and IL-6 (6,7). Treatments specifically targeting both of these cytokines are now available, and recently there has been a significant increase in the amount of published data regarding their efficacy. Furthermore, approximately 10% of children with systemic JIA develop overt clinical features of macrophage activation syndrome (MAS), a life-threatening condition characterized by fever, organomegaly, cytopenias, hyperferritinemia, hypertriglyceridemia, hypofibrinogenemia, and coagulopathy, among other findings (7–9). The mortality rate for children hospitalized with systemic JIA and MAS is estimated to be as high as 6%, but may even be higher based on estimates from case series (10,11). Systemic JIA is therefore the focus of this update, providing the opportunity to address the treatment of this unique inflammatory process and associated MAS features.

In addition, in response to public comment, this update also includes recommendations for repeat tuberculosis (TB) screening for all categories of JIA patients receiving biologic agents, in order to address questions about followup screening for children receiving these medications for longer durations and the risk of false-positive results associated with annual TB screening performed without regard for risk factors.

As with the previously published ACR recommendations and as specified by the RAND/University of California, Los Angeles (UCLA) Appropriateness Method, cost implications were not considered in assembling these recommendations. The use of combination therapy with a biologic agent was also not considered, due to safety concerns and lack of data. Furthermore, as with the original 2011 ACR JIA treatment recommendations, the results of this project should be considered "recommendations," and are meant to serve as a reference for health care providers caring for children with JIA. These recommendations are not intended to take the place of physician judgment and shared decision making with patients and are not intended to limit the coverage of medications used in the treatment of JIA. Likewise, these recommendations are intended to offer guidance for providers caring for children with the most common phenotypes associated with systemic JIA, rather than exceptional cases with unusual disease manifestations or refractory disease.

A document containing the 2011 ACR JIA treatment recommendations and the 2013 updated recommendations is provided in Supplementary Appendix A

Ontario, Canada; [8]Peter A. Nigrovic, MD: Brigham and Women's Hospital, Boston, Massachusetts; [9]Angela Byun Robinson, MD, MPH: Rainbow Babies and Children's Hospital, Cleveland, Ohio; [10]Richard K. Vehe, MD: University of Minnesota, Minneapolis.

Dr. Beukelman has received consulting fees from Genentech and McKesson Health Solutions (less than $10,000 each) and from Novartis (more than $10,000). Dr. Ilowite has received consulting fees, speaking fees, and/or honoraria from Janssen and Novartis (less than $10,000 each). Dr. Kimura has received consulting fees, speaking fees, and/or honoraria from Novartis (less than $10,000). Dr. Laxer has received consulting fees, speaking fees, and/or honoraria from Novartis (less than $10,000) and receives royalties from *Textbook of Pediatric Rheumatology*. Dr. Lovell has received consulting fees, speaking fees, and/or honoraria from Novartis and Hoffman-La Roche (less than $10,000 each). Dr. Nigrovic has received consulting fees from Novartis (less than $10,000).

Drs. Ringold and Weiss contributed equally to this work.

Submitted for publication March 5, 2013; accepted in revised form July 2, 2013.

(available in the online version of this article at http://onlinelibrary.wiley.com/doi/10.1002/art.38092/abstract).

MATERIALS AND METHODS

The ACR reviews its recommendations approximately annually to determine whether a partial update or full revision is warranted, based on changes in supporting evidence and available therapies. In early 2012, the ACR decided that an update to its 2011 JIA recommendations was necessary, specifically in the area of systemic JIA. The ACR leadership subsequently approached the team of investigators who had developed the 2011 JIA guidelines and, through discussions with this group and additional pediatric rheumatologists, assembled a new team to develop the 2013 JIA update.

This project complied with ACR guideline development policies related to disclosure and conflicts of interest. All participants disclosed their relationships at several different points during the process. Disclosures were specifically shared with other participants (e.g., in writing and verbally during meetings), posted online as part of the protocol released for public comment, disclosed during manuscript review, and disclosed in the final manuscript. Per ACR policy, no more than 49% of the Core Expert Panel (CEP) and Task Force Panel (TFP) members had conflicts of interest at any time during this project, and the principal investigators (PIs; SR and PFW) maintained their unconflicted status throughout the project.

The recommendations were developed using the RAND/UCLA Appropriateness Method, which was also used in the development of the 2011 ACR JIA treatment recommendations (1,12). A CEP, consisting of 11 pediatric rheumatologists experienced in the management of JIA and actively involved in JIA research, assisted with refining the scope of this update, developing the literature search strategy and Evidence Report, and finalizing the clinical scenarios. A TFP, consisting of 12 experts in the field of JIA, including participants from Europe and Canada, participated in 2 rounds of voting on the clinical scenarios. Effort was made to include participants from different geographic locations, with variable time since completion of training and different practice focuses. Thirteen of the CEP and TFP participants also had been involved in the development of the 2011 ACR JIA treatment recommendations.

During the voting rounds, members of the TFP rated the appropriateness of each scenario using a 1–9 ordinal scale, as recommended by the RAND/UCLA method (12). Prior to voting, members of the TFP received a Voter's Handbook that included detailed descriptions of the clinical scenarios and voting instructions, and an Evidence Report summarizing results of the systematic review described below. In the first round, the TFP members cast their votes independently by e-mail. At the subsequent face-to-face meeting, TFP members received a summary of the group's anonymous responses for each scenario, with their own individual responses and the group median responses clearly indicated. Discussions at the face-to-face meeting focused primarily on scenarios where there was disagreement among the TFP members, with the goal of the discussion being not to force consensus, but to ensure that all panel members understood and interpreted the scenario and the available evidence in a similar way. A general pediatrician and evidence-based medicine expert and a parent of a child with systemic JIA also participated in the face-to-face meeting discussion to provide additional perspective and input, but did not vote.

Scope of the recommendations. The overarching objective of this project was to update the 2011 ACR recommendations for the use of nonbiologic disease-modifying antirheumatic drugs (DMARDs) and biologic DMARDs in the treatment of systemic JIA. The specific aims of the project were to 1) update the 2011 ACR recommendations regarding indications for starting nonbiologic DMARDs and biologic DMARDs for systemic JIA and indications for switching between nonbiologic DMARDs and biologic DMARDs for systemic JIA; 2) incorporate the use of anti–IL-1 and anti–IL-6 therapies into the ACR recommendations for the treatment of systemic JIA; and 3) develop treatment recommendations for patients with the following 3 general systemic JIA phenotypes: significant systemic features and varying degrees of synovitis, significant arthritis and no significant systemic features, and features concerning for MAS. The aims were specified in the project protocol that was posted online for public comment by the ACR from June to July 2012. In response to public comment, an additional aim was added to the scope to provide recommendations for repeat annual TB screening among children with all categories of JIA who had a negative baseline TB evaluation.

Development of the Evidence Report. *Systematic literature review.* The literature search strategy was developed by the project's PIs (SR and PFW), a medical research librarian, and the CEP. The search strategy underwent peer review by an additional medical librarian using Peer Review of Electronic Search Strategies (13). The search strategies are included in Supplementary Appendix B (available in the online version of this article at http://onlinelibrary.wiley.com/doi/10.1002/art.38092/abstract).

The following electronic databases were searched: Ovid MEDLINE, Embase, PubMed, and Cochrane Library (Wiley). For medications included in the 2011 ACR JIA treatment recommendations, these databases were searched from October 6, 2009 (the end date of the literature search for the 2011 ACR JIA treatment recommendations) through July 25, 2012 (Table 1). For medications not included in the 2011 recommendations, the databases were searched from their beginning through July 25, 2012. In addition, each database was searched in its entirety for the treatment of MAS in systemic JIA. The same databases were searched for TB screening and JIA from October 6, 2009 through September 5, 2012.

Conference abstracts were searched for preliminary reports of randomized clinical trials for which the final results were not yet published. Embase was searched for conference abstracts relating to all of the medications included in this update between January 1, 2010 and July 27, 2012. ClinicalTrials.gov was also searched to identify any additional studies with potentially relevant results that were not yet published. Two articles were in submission at the time of the first TFP votes and were included in the Evidence Report, with permission from the authors, to provide the TFP with the most current evidence (14,15). Both articles were in press by the time of the face-to-face meeting, and have subsequently been published.

Table 1. Medications evaluated for the treatment of systemic juvenile idiopathic arthritis*

	2011 recommendations	2013 recommendations
NSAIDs†	X	X
Glucocorticoids	X	X
Methotrexate	X	X
Leflunomide	X	X
IVIG	X	X
Calcineurin inhibitors‡	X	X
TNFα inhibitors§	X	X
Abatacept	X	X
Rituximab	X	X
Anakinra	X	X
Canakinumab		X
Rilonacept		X
Tocilizumab		X

* NSAIDs = nonsteroidal antiinflammatory drugs; IVIG = intravenous immunoglobulin; TNFα = tumor necrosis factor α.
† Includes all NSAIDs commonly used in clinical practice in the US, including selective cyclooxygenase 2 inhibitors.
‡ Cyclosporine and tacrolimus.
§ Adalimumab, etanercept, and infliximab.

An updated search was performed for all sources through January 14, 2013 in order to ensure that more recently published articles were also available for citation. An evaluation of the literature search results was performed by the PIs (SR and PFW) to determine whether any of the newly identified articles would change the recommendations, but none were deemed contradictory to the recommendations made by the TFP, and therefore it was determined that additional consideration of these articles by the TFP was not necessary.

Criteria for study inclusion/exclusion. Studies were included in the Evidence Report if they comprised children (defined as participants ages <18 years) with systemic JIA and if they specifically addressed the treatment of systemic JIA and/or the safety of medications used in this context.

Studies in languages other than English were excluded, as were non-systematic review articles, commentaries, and consensus statements. Articles that reported mechanistic aspects of therapy and did not describe the clinical characteristics of patients or their outcomes were excluded. Studies that assessed only costs were also excluded, as specified by the guideline scope and the RAND/UCLA method.

Development of the Evidence Report. The titles and abstracts of the 2,200 articles identified by the initial search were screened by a panel of volunteers consisting of a medical student, fellows, and junior faculty in pediatric rheumatology (see Acknowledgments), and articles not fulfilling the inclusion criteria were removed. If it was unclear whether an article should be included, it was kept on the list of potentially eligible articles. The full text of each potentially eligible article then underwent additional screening by a volunteer, who gave the article a final determination regarding inclusion/exclusion and extracted relevant data for the Evidence Report. If the reviewer was uncertain about the article's eligibility, the article underwent additional review by one of the PIs (SR), who also reviewed each article's final determination.

A total of 125 articles were included in the final Evidence Report. Three articles were subsequently included from the updated literature search. The data abstracted from each article for the Evidence Report included study design, participants (number and diagnosis), medication (including dose), concurrent medications, inclusion criteria, exclusion criteria, baseline disease measures, primary and secondary outcomes, adverse events, and limitations. If children with different categories of JIA were included in a study, reviewers were asked to document the results for systemic JIA patients separately, whenever possible. The abstracted data were reviewed for clarity and completeness by one of the PIs (SR), and additional data abstraction was performed when needed. Summaries of specific articles from the 2011 Evidence Report were also included in the new report, when relevant. The entire Evidence Report used for the development of the 2011 ACR JIA recommendations was also made available to the TFP members for review, upon request.

Development of the clinical scenarios. Clinical scenarios were developed by the PIs (SR and PFW) with input from the CEP based on the 3 primary phenotypes (see below). The features of poor prognosis and levels of disease activity specified in the 2011 ACR JIA recommendations were not applied to the scenarios in this update based on input from the CEP that these characteristics were of unclear relevance to decision making at the point of care for patients with systemic JIA. The consensus opinion of the CEP was that certain features of poor prognosis (i.e., joint erosions) are often not known or pertinent in new-onset cases. The choice of disease activity variables and their decision thresholds was made using an iterative process via e-mail and teleconferences with repeated revision until they were accepted by all CEP members. For each scenario, there was consensus among CEP members that the disease activity variables included provided a meaningful clinical threshold relevant for treatment decisions. The decision thresholds of active joint count (AJC; $\leq$4 or >4) and physician global assessment (MD global; <5 or $\geq$5) were chosen by CEP consensus. Disease activity descriptors were also limited to restrict the number of scenarios in order to avoid voter fatigue (12). Medication monitoring was not specifically addressed in these scenarios because it was determined that monitoring recommendations for the medications included in this project would not be expected to differ from those of the 2011 ACR JIA recommendations and/or the publicly available recommendations included in the package inserts for each of these medications. Three primary clinical phenotypes were developed. In each case, it was specified that the participants had met the International League of Associations for Rheumatology criteria for systemic JIA at disease onset (2).

For the first phenotype, systemic JIA with active systemic features and varying degrees of synovitis, active systemic features were defined as the presence of any combination of the following disease features: fever, evanescent rash, lymphadenopathy, hepatomegaly, splenomegaly, or serositis. Rather than considering specific combinations of these manifestations, the TFP was asked to consider the treatments among patients with an MD global of <5 or $\geq$5 on a 10-point numerical rating scale and by AJC (0 joints, 1–4 joints, or >4 joints).

For the second phenotype, systemic JIA without active systemic features but with active synovitis, TFP members were

asked to rate the appropriateness of medical therapies based on the total number of active joints (≤4 joints or >4 joints).

For the third phenotype, systemic JIA with features concerning for MAS, features concerning for MAS were defined as any combination of the following disease manifestations: persistent (rather than quotidian) fever, cytopenias or falling cell line counts (particularly platelets), falling erythrocyte sedimentation rate, hypertriglyceridemia, hypofibrinogenemia, hemophagocytosis, transaminitis, coagulopathy, organomegaly, low or absent natural killer cell activity, hyperferritinemia, or central nervous system dysfunction. This definition was left intentionally broad given the lack of validated classification criteria for MAS. The scenarios specifically excluded critically ill patients requiring intensive care unit admission.

A separate scenario was developed to address repeat TB screening among all categories of JIA patients receiving biologic agents. The TFP was asked to consider the appropriateness of different screening approaches for TB, including annual screening and risk-based approaches. The TFP did not consider the method of screening (e.g., interferon-γ–release assay versus tuberculin skin test).

Medications, duration of therapy, and doses used in clinical scenarios. The medications addressed in the guideline scenarios are shown in Table 1. For each scenario, it was assumed that prior medications were given for a minimum of 3 months, with the exceptions of 1) anakinra, for which the duration was defined as ≥1 month; 2) nonsteroidal antiinflammatory drug (NSAID) monotherapy, for which the maximum duration was defined as 1 month; and 3) systemic glucocorticoid (GC) monotherapy, for which the maximum duration was defined as 2 weeks. The duration of anakinra was discussed with the CEP at large prior to the TFP voting, and 4 weeks was the timeframe agreed upon for an expected response. The duration of NSAID monotherapy and systemic GC monotherapy was voted on by the TFP.

There was no consideration of combination therapy with a biologic agent. When biologic agents were evaluated as sequential therapy, it was indicated that prior biologic agents were discontinued before initiation of a new one. For the scenarios that addressed the sequential therapy of patients with active systemic features, the TFP voting panel was instructed that these patients could be assumed to be receiving concurrent systemic GC therapy (with the exception of the scenario used to determine the duration of NSAID monotherapy, in which adjunct systemic GCs were specifically excluded) and that they should rate the appropriateness of initiating the medication under consideration either with or without concurrent initiation or increase of GC therapy (whichever approach was considered more appropriate by the voter). Receipt of concurrent GC therapy was not assumed for those scenarios that addressed the treatment of patients without active systemic features but with active synovitis. Tumor necrosis factor α (TNFα) inhibitors were considered together as a single group rather than as individual medications. Different IL-1 inhibitors were considered separately for the scenarios that addressed initiation of the medication because it was determined by the CEP that currently available data could inform this choice. For scenarios that considered IL-1 inhibitors as sequential therapy, these medications were considered as a group rather than separate medications, both to restrict the number of scenarios and because it was determined there would be sparse data to inform the use of a specific IL-1 inhibitor in this situation. For all recommendations, it was also assumed that patients received the typical maximum dose of each medication. Although higher doses of these medications may be appropriate in certain clinical situations, these situations were not specifically considered by the TFP.

In order to limit the number of clinical scenarios on which the TFP would vote, the issue of whether a nonbiologic DMARD and a biologic agent could be combined or whether they would only be used sequentially was left to the provider's discretion.

Rating of the clinical scenarios by the TFP. The TFP members were asked to rate the appropriateness of the interventions in each of the clinical scenario permutations using the Evidence Report, as well as their best clinical judgment. "Appropriateness" was defined as "the health benefits exceed the health risks by a sufficiently wide margin that the intervention is worth doing" (12). The decision to recommend or not recommend initiation of a medication for a particular scenario included the risk of not initiating an alternative therapy (e.g., the risk of initiating drug A includes the risk of not initiating drug B). Each scenario was scored on a numerical rating scale from 1–9, where 1–3 = "inappropriate," 4–6 = "uncertain," and 7–9 = "appropriate." An uncertain score indicated that either the risks or benefits were approximately equal or there was not enough information available for the TFP to make a meaningful evaluation.

Developing recommendations from the TFP votes. The second round of votes from the face-to-face meeting was used to create the final recommendations. Therapies are listed as "recommended" if they met the RAND/UCLA appropriateness definition that includes a median score of 7–9 and no disagreement. Therapies listed as "inappropriate" had a median in the range of 1–3 and no disagreement. Disagreement was defined as at least 3 panelists rating the indication between 1 and 3 and at least 3 panelists rating the indication between 7 and 9. "Uncertain" indications had a median in the range of 4–6 or disagreement regardless of the median score.

Rating of the evidence supporting the final ACR recommendations. Following the development of recommendations, a level of evidence was assigned to each recommendation using the system proposed by the Oxford Centre for Evidence-Based Medicine (16). This is the same rating system used for the 2011 ACR JIA treatment recommendations. Briefly, this rating system creates the following 4 categories for rating evidence: A = randomized controlled trials; B = nonrandomized studies, including retrospective cohort studies; C = uncontrolled studies, including case series; and D = expert opinion. Level B was also assigned to any recommendation for which there was extrapolation from randomized controlled trials. Level C was also assigned to any recommendation for which there was extrapolation from a nonrandomized study or more complex extrapolation from a randomized controlled trial. The level of evidence assigned reflects the highest rating achieved for each recommendation (i.e., if studies in support of a recommendation have a level of evidence ranging from B–D, the overall level of evidence is reported as B). In order to provide the most comprehensive reference list, all relevant

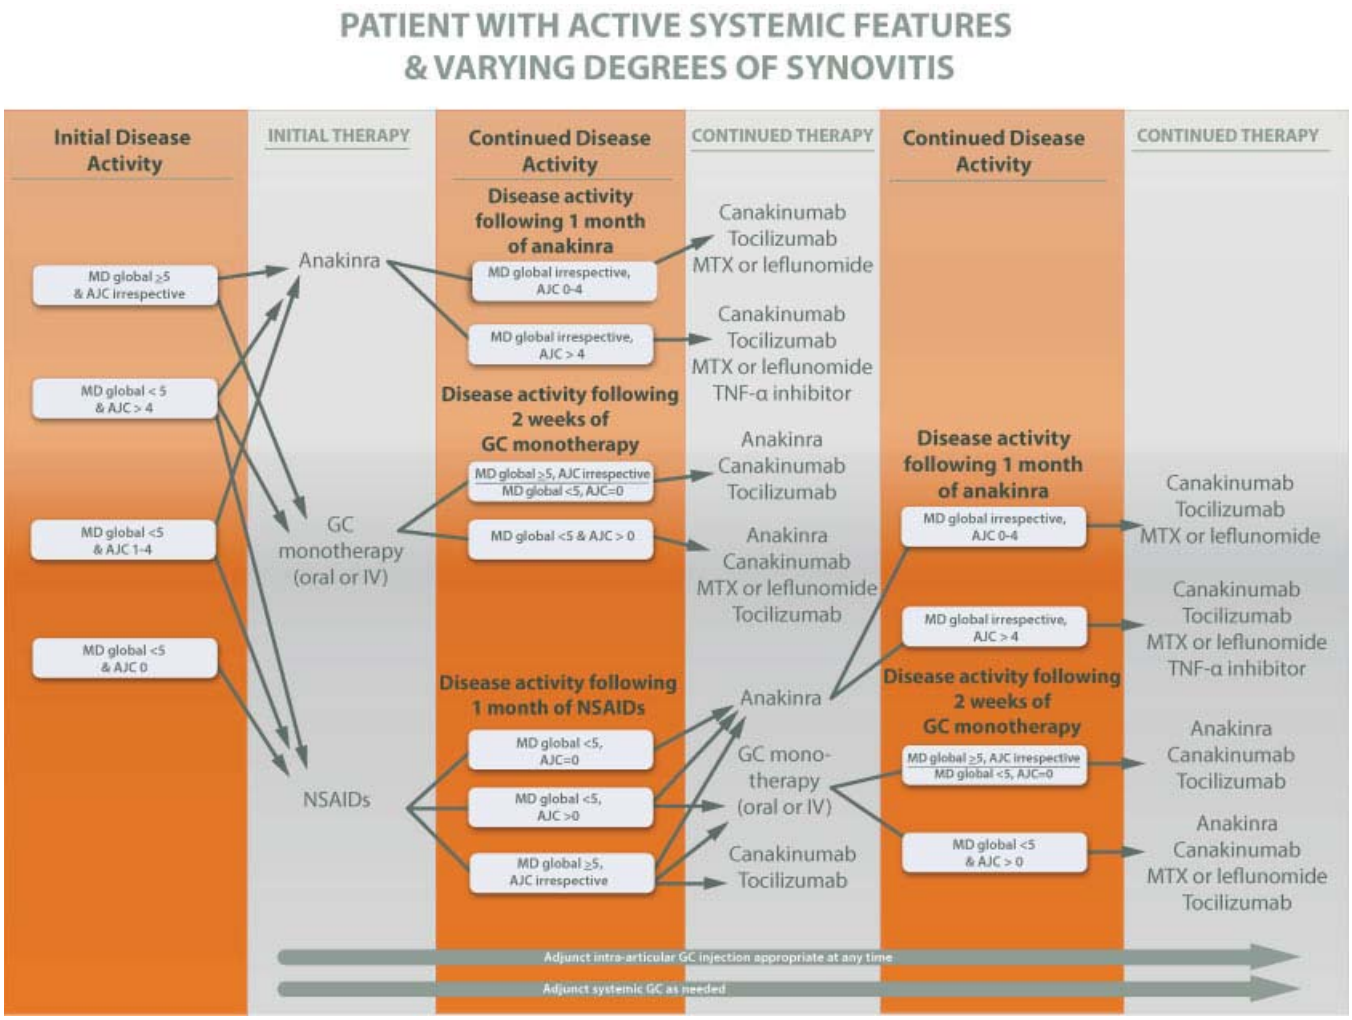

Figure 1. Treatment pathways for patients with active systemic features and varying degrees of synovitis. The Task Force Panel was asked to consider the treatments among patients with active systemic features and a physician global assessment (MD global) of <5 or ≥5 on a 10-point numerical rating scale (0–10 visual analog scale, where 0 = no disease activity and 10 = the most severe) and by active joint count (AJC; 0 joints, 1–4 joints, or >4 joints). If a recommendation is noted to be irrespective of the AJC or MD global, the recommendation was for children with an AJC ≥0 or an MD global >0, respectively. Adjunct systemic glucocorticoids (GCs) and/or intraarticular GCs may be added at any point. Children may qualify for >1 pathway, in which case it is left to the provider's discretion to choose the path they feel is most appropriate based upon specific patient characteristics and/or patient and family preferences. Steps in the progression of therapy can be additive or sequential, except that therapies with a biologic agent are sequential (combination therapy with a biologic agent is not endorsed). The recommendations in this figure are for patients with active systemic features. If the systemic features (but not the arthritis) respond to therapy, then subsequent treatment decisions should be based upon the recommendations in Figure 2. NSAIDs = nonsteroidal antiinflammatory drugs; IV = intravenous; MTX = methotrexate; TNFα = tumor necrosis factor α.

articles from the Evidence Report are cited, even if they did not provide the highest level of evidence.

RESULTS

The recommendations for initiation of various therapeutic agents are listed separately for the following clinical phenotypes of systemic JIA: 1) active systemic features and varying degrees of synovitis, 2) no active systemic features and varying degrees of active synovitis, and 3) features concerning for MAS. Recommended initial therapeutic options are listed first, in alphabetical order. Therapeutic options for continued disease activity after initial therapy are listed next, in alphabetical order. Medications that were considered by the TFP but were

determined to be inappropriate or uncertain (and were not recommended for any of the related scenarios) are listed at the end of each section, in alphabetical order. The assigned level of evidence and corresponding publication citations follow each treatment recommendation. If a recommendation is noted to be irrespective of the AJC or MD global, the recommendation was for children with an AJC ≥0 or an MD global >0, respectively. Continued disease activity, as used in the recommendations below, was defined as an AJC >0 and/or an MD global >0. In some cases, children may qualify for more than one pathway, in which case it is left to the provider's discretion to choose the path they feel is most appropriate based upon specific patient characteristics and/or patient and family preferences.

Systemic JIA with active systemic features and varying degrees of synovitis. The treatment recommendations for this group of patients are shown in Figure 1. The TFP was asked to consider the treatments among patients with an MD global of <5 or ≥5 on a 10-point numerical rating scale and by AJC (0 joints, 1–4 joints, or >4 joints). The TFP voting panel was informed that these patients could be assumed to be receiving concurrent systemic GC therapy and that they should rate the appropriateness of initiating the medication under consideration either with or without concurrent initiation or increase of GC therapy (whichever approach was considered more appropriate by the voter). The recommendations in this section are for patients with active systemic features. If the systemic features (but not the arthritis) respond to therapy, then subsequent treatment decisions should be based upon recommendations in the next section, "Systemic JIA without active systemic features and with varying degrees of active synovitis."

Initial therapeutic options (listed alphabetically). Anakinra was recommended as one initial therapeutic option for patients with an MD global ≥5 irrespective of the AJC, or an MD global <5 and an AJC >0 (level C) (17–19).

Systemic GC monotherapy (administered by oral or intravenous route) was recommended for a maximum period of 2 weeks as a therapeutic option for patients with an MD global <5 and an AJC >4 and for all patients with an MD global ≥5 irrespective of the AJC (level C) (20,21). Continuing GCs as monotherapy for ≥1 month for patients with continued disease activity was inappropriate (level D). The minimum duration of GC monotherapy and specific tapering regimens for GCs were not specifically addressed by the TFP.

Initiating NSAID monotherapy in a patient without prior treatment was recommended as one approach for patients with an MD global <5 irrespective of the AJC (level D). NSAID monotherapy was inappropriate for patients with an MD global ≥5 and an AJC >0 (level D). Continuing NSAID monotherapy for longer than 1 month for patients with continued disease activity was inappropriate (level D). The minimum duration of a trial of NSAIDs was not specifically addressed by the TFP.

Therapeutic options for continued disease activity (listed alphabetically). Use of abatacept was recommended only for patients with an MD global ≥5 and an AJC >4 after a trial of both an IL-1 inhibitor and tocilizumab (sequentially) (level D). Use of abatacept for patients with an AJC of 0 irrespective of the MD global was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially), in which case it was uncertain. Use of abatacept for patients with an MD global <5 and an AJC >0 or an MD global ≥5 and an AJC <4 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially) or a DMARD plus either an IL-1 inhibitor or tocilizumab, in which case it was uncertain. Use of abatacept for patients with an MD global ≥5 and an AJC >4 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially), in which case it was appropriate (level D), or patients who had tried a DMARD plus either an IL-1 inhibitor or tocilizumab, in which case it was uncertain.

Anakinra was recommended for patients with continued disease activity after treatment with GC monotherapy (level A) (17,18,22–30) or NSAID monotherapy (level C) (17,18,22,28).

Use of a calcineurin inhibitor was recommended only for patients with an MD global ≥5 and an AJC of 0 after a trial of both an IL-1 inhibitor and tocilizumab (sequentially) (level C) (31–36). Use of a calcineurin inhibitor for patients with an MD global <5 and an AJC of 0 was inappropriate (level D), with the exception of patients who received either an IL-1 inhibitor or tocilizumab, in which case it was uncertain. Use of a calcineurin inhibitor for patients with an MD global ≥5 and an AJC of 0 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially), in which case it was appropriate (level C) (31–36), or patients who had tried an IL-1 inhibitor or tocilizumab, in which case it was uncertain. Use of a calcineurin inhibitor for patients with an AJC >0 irrespective of the MD global was inappropriate (level D), with the exception of patients

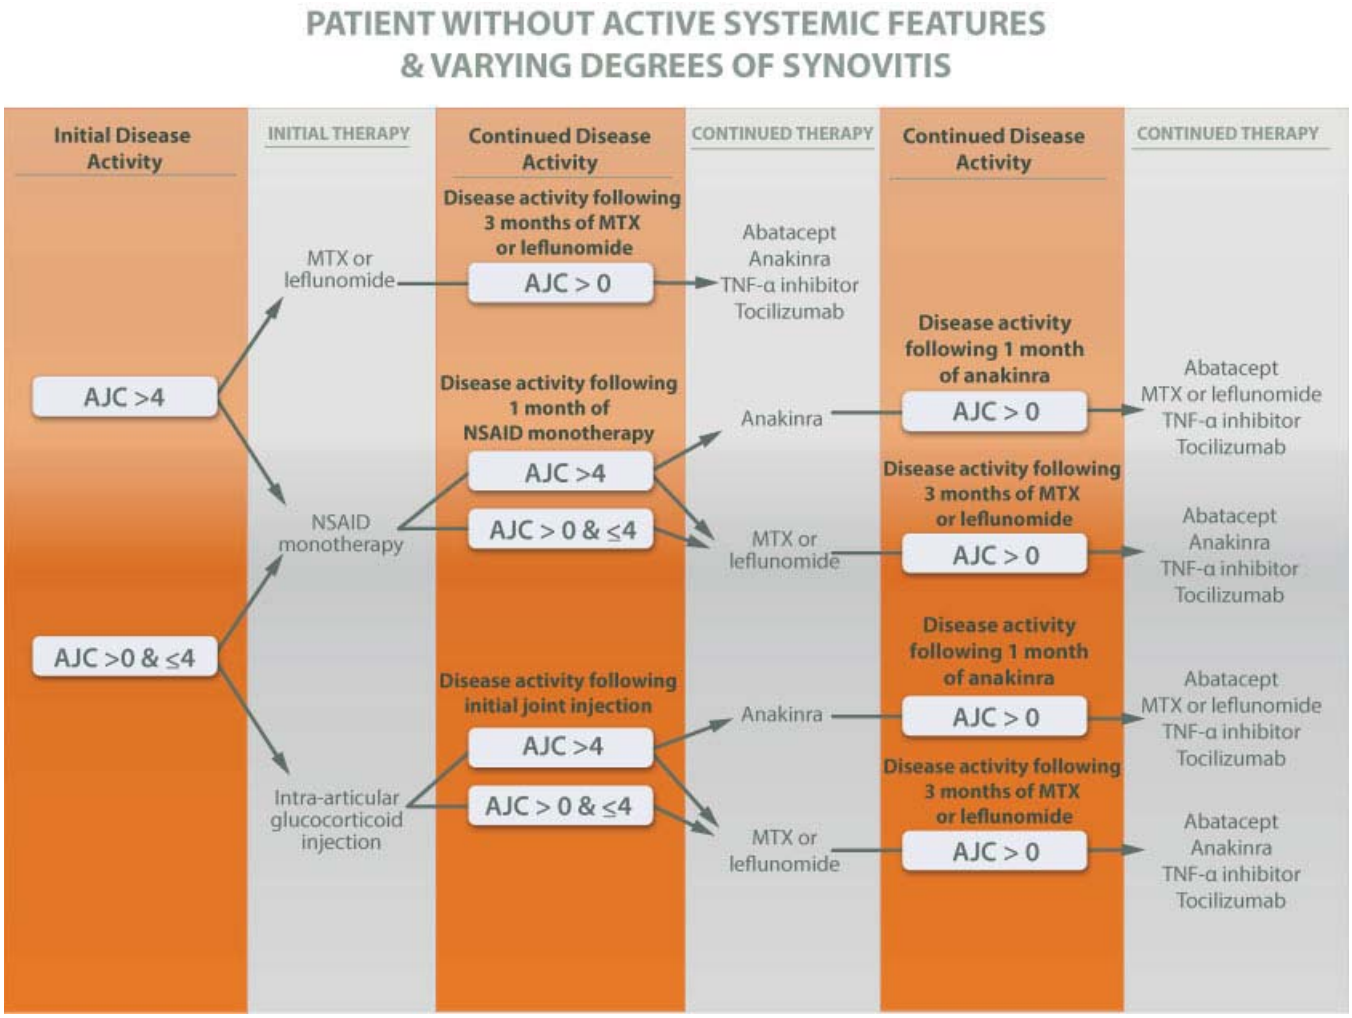

Figure 2. Treatment pathways for patients without active systemic features and with varying degrees of synovitis. The Task Force Panel was asked to rate the appropriateness of therapies based on the total number of active joints (≤4 or >4). Children may qualify for >1 pathway, in which case it is left to the provider's discretion to choose the path they feel is most appropriate based upon specific patient characteristics and/or patient and family preferences. Steps in the progression of therapy can be additive or sequential, except that therapies with a biologic agent are sequential (combination therapy with a biologic agent is not endorsed). AJC = active joint count; MTX = methotrexate; NSAID = nonsteroidal antiinflammatory drug; IV = intravenous; TNFα = tumor necrosis factor α.

who had tried both an IL-1 inhibitor and tocilizumab (sequentially) or an alternate DMARD plus either an IL-1 inhibitor or tocilizumab, in which case it was uncertain.

Canakinumab was recommended for patients with continued disease activity after treatment with GC monotherapy (level A) (14,37), methotrexate (MTX) or leflunomide (level A) (14,37), anakinra (level B) (14,37), or tocilizumab (level C) (14,37) irrespective of the MD global and AJC. Canakinumab was also recommended for patients with an MD global ≥5 irrespective of the AJC, despite prior NSAID monotherapy (level C) (14,37).

GC monotherapy was recommended as an option following failed treatment with NSAID monotherapy for patients with an MD global <5 and an AJC >0 and for patients with an MD global ≥5 irrespective of the AJC (level C) (20,21). Adjunct GC therapy at any point was appropriate to consider (level D).

Intraarticular GC injection was recommended as adjunct therapy at any time (level C) (38,39).

MTX or leflunomide was recommended for pa-

tients with an MD global <5 and an AJC >0 after treatment with GC monotherapy (level C) (40), an IL-1 inhibitor (level D), or tocilizumab (level D). MTX or leflunomide was recommended for patients with an MD global ≥5 and an AJC >0, only after a trial of an IL-1 inhibitor or tocilizumab (level C) (40). Initiation of MTX or leflunomide was inappropriate for patients with an AJC of 0 irrespective of the MD global (level D).

Initiation of a TNFα inhibitor was recommended for patients with an AJC >4 irrespective of the MD global after a trial of an IL-1 inhibitor or tocilizumab (level C) (41,42). Initiation of a TNFα inhibitor was recommended for patients with an AJC >0 irrespective of the MD global after a trial of both an IL-1 inhibitor and tocilizumab (sequentially) (level C) (41,42). Use of a TNFα inhibitor for patients with an MD global <5 and an AJC of 0 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially) or a DMARD plus either an IL-1 inhibitor or tocilizumab, in which case it was uncertain. Use of a TNFα inhibitor for patients with an MD global ≥5 and an AJC of 0 was inappropriate (level D), with the exception of patients who had tried an IL-1 inhibitor or tocilizumab, in which case it was uncertain.

Tocilizumab was recommended as a therapeutic option for patients with continued disease activity following GC monotherapy (level A) (15,43–49), MTX or leflunomide (level B) (15,43–49), or anakinra (level B) (15) irrespective of the MD global and AJC. Tocilizumab was also recommended for patients with an MD global ≥5 irrespective of the AJC despite prior NSAID monotherapy (level C) (15,43–49).

Uncertain or inappropriate options for continued disease activity (listed alphabetically). Use of IVIG was inappropriate irrespective of the AJC and MD global (level D).

Use of nonbiologic DMARD combination therapy (MTX plus leflunomide and/or a calcineurin inhibitor) was uncertain irrespective of the AJC and MD global.

Use of rilonacept was inappropriate as initial therapy irrespective of the MD global and AJC (level D). Use of rilonacept was uncertain for continued disease activity after a trial of other therapeutic options irrespective of the AJC and MD global.

Use of rituximab was inappropriate for patients with an AJC of 0 irrespective of the MD global. Use of rituximab for patients with an MD global <5 and an AJC <4 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially), in which case it was uncertain. Use of rituximab for patients with an MD global <5 and an AJC >4 or an MD global ≥5 and an AJC >0 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially) or a DMARD plus either an IL-1 inhibitor or tocilizumab, in which case it was uncertain.

Systemic JIA without active systemic features and with varying degrees of active synovitis. The treatment recommendations for this group of patients are shown in Figure 2. The TFP was asked to rate the appropriateness of therapies based on the total number of active joints (≤4 joints or >4 joints). Each of the recommendations below is irrespective of the MD global.

Initial therapeutic options (listed alphabetically). Intraarticular GC injection was recommended as an initial treatment option for patients with an AJC ≤4 (level C) (38,39). Intraarticular GC injection as the only therapeutic intervention was uncertain for patients with an AJC >4. The utility of repeating intraarticular injection as the only intervention was uncertain in a joint or joints currently affected.

Initiation of MTX or leflunomide was recommended for patients with an AJC >4 (level C) (40,50–53).

Initiation of NSAID monotherapy in a patient without prior treatment for a maximum period of 1 month was recommended as one treatment approach for patients with an AJC >0 (level D). Continuing NSAID monotherapy for longer than 2 months for patients with continued disease activity was inappropriate (level D). The minimum duration of a trial of NSAIDs was not specifically addressed by the TFP.

Therapeutic options for continued disease activity (listed alphabetically). Use of abatacept was recommended for patients with an AJC >0 after treatment with MTX or leflunomide (level B) (54–57), anakinra (level D), or tocilizumab (level D).

Anakinra was recommended as a therapeutic option for patients with an AJC >4 following failed intraarticular injection or NSAID monotherapy (level B) (29,58). Use of anakinra was also recommended for patients with an AJC >0 following treatment with MTX or leflunomide (level B) (22,29,30,58).

Initiation of canakinumab was recommended for patients with an AJC >4 only after a trial of a DMARD plus anakinra or tocilizumab (level B) (14,37), a DMARD plus a TNFα inhibitor (level B) (14,37), or abatacept (level C) (14,37).

Use of MTX or leflunomide was recommended as an option for an AJC >0 following treatment with intraarticular injection (level C) (51,52), NSAID monotherapy (level C) (51,52), an IL-1 inhibitor (level D), or tocilizumab (level D).

Initiation of a TNFα inhibitor was recommended for patients with an AJC >0 after treatment with MTX or leflunomide (level C) (59–61), anakinra (level D), or tocilizumab (level D).

Initiation of tocilizumab was recommended for an AJC >0 following treatment with anakinra (level B) (15) or MTX or leflunomide (level B) (15).

Uncertain or inappropriate options for continued disease activity (listed alphabetically). Initiation of nonbiologic DMARD combinations (MTX plus leflunomide and/or a calcineurin inhibitor) was uncertain irrespective of the AJC.

Initiation of rilonacept was uncertain irrespective of the AJC.

Use of rituximab for patients with an AJC ≤4 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially) or a DMARD in combination with an IL-1 inhibitor or tocilizumab, in which case it was uncertain. Use of rituximab for patients with an AJC >4 was inappropriate (level D), with the exception of patients who had tried both an IL-1 inhibitor and tocilizumab (sequentially) or a DMARD in combination with an IL-1 inhibitor, tocilizumab, a TNFα inhibitor, or abatacept, in which case it was uncertain.

Systemic JIA with features concerning for MAS. The recommendations for treatment of patients with systemic JIA and features concerning for MAS are described below. These treatment options are not meant to be mutually exclusive and there may be certain clinical situations for which the simultaneous initiation of more than one of these medications is appropriate. Combination therapy with anakinra, a calcineurin inhibitor, and systemic GCs was not specifically addressed.

Initial therapeutic options (listed alphabetically). Use of anakinra was recommended as one therapeutic option for patients with features concerning for MAS (level C) (18,19,28,62–64).

Use of a calcineurin inhibitor was recommended as one therapeutic option for patients with features concerning for MAS (level C) (65–69).

Use of systemic GC monotherapy (administered by oral or intravenous route) was also recommended as a therapeutic option for patients with features concerning for MAS (level C) (70,71). Continuing GC monotherapy for ≥2 weeks in patients with continued features concerning for MAS was inappropriate (level D). Specific tapering strategies for GCs were not specifically addressed by the TFP.

Uncertain or inappropriate options for continued disease (listed alphabetically). Initiation of abatacept was inappropriate (level D).

Use of canakinumab was uncertain, with the exception of patients with an MD global <5 who had received no prior therapy, GC monotherapy, or calcineurin monotherapy, in which case it was inappropriate (level D).

Use of IVIG was inappropriate (level D), with the exception of patients who had tried a calcineurin inhibitor in combination with anakinra, in which case it was uncertain.

Use of MTX or leflunomide was inappropriate (level D).

Use of rilonacept was uncertain.

Use of rituximab was inappropriate (level D).

Use of a TNFα inhibitor was inappropriate irrespective of the MD global (level D), with the exception of patients who had tried a calcineurin inhibitor in combination with anakinra, in which case it was uncertain.

Use of tocilizumab was uncertain.

Repeat testing for latent TB for children with all categories of JIA. Annual screening of children at low risk of TB with an initial negative TB test was inappropriate (level D). It was recommended that patients with an initial negative TB test prior to starting a biologic agent have TB screening repeated at any point if their risk of TB changed to moderate or high, as determined by regional infectious disease guidelines (level D).

DISCUSSION

These recommendations for the treatment of systemic JIA and secondary TB screening are the culmination of a systematic review and formal evaluation of 1,226 scenarios using the RAND/UCLA methodology by an international panel of experts in the field of JIA and pediatric rheumatology, with input from an expert in evidence-based medicine and from the parent of a child with systemic JIA. This current work represents an update of the 2011 ACR JIA treatment recommendations that included recommendations for systemic JIA with systemic features, but due to limitations of data at the time, did not provide recommendations for specific phenotypes of systemic JIA. Since the publication of these initial recommendations, data from randomized trials of new IL-1 inhibitors and IL-6 inhibitors in

children with systemic JIA have been published, supporting the need for updated recommendations including these medications (14,15).

These recommendations should be interpreted in the context of several limitations. First, systemic JIA is a complex disease with heterogeneous manifestations. The phenotypes and scenarios used in the development of these recommendations do not represent all possible patient presentations. The specific influence of disease features such as hip arthritis, rash, and fever was not evaluated; the assumption of the CEP was that fever and other relevant systemic features would be reflected in the MD global. The lack of a standardized disease activity score also limited the development of clinical scenarios, and the categorization of disease severity by the AJC and MD global may also limit the scenarios' representation of the variety of possible patient presentations. The decision thresholds of AJC (≤ 4 or >4) and MD global (<5 and ≥ 5) were chosen by CEP consensus. Their validity may be scrutinized in the future by examining their relationship with therapeutic decisions in standard clinical practice and with criteria for enrolling patients in randomized clinical trials.

Several recommendations were assigned level of evidence A because there was at least one well-designed randomized clinical trial to help inform the recommendation. For example, the level A evidence available to support the use of anakinra after treatment with GC monotherapy for children with active systemic features is the ANAJIS trial, which is a randomized trial, but it is a single trial that enrolled only 24 patients, making it necessary to interpret efficacy and safety data with some caution. The conclusions of ANAJIS are borne out from multiple case series that reached the same conclusion. Furthermore, because many of these recommendations are derived from expert opinion (level of evidence D) rather than higher levels of evidence, these recommendations may require revision as new data are generated regarding treatment efficacy, effectiveness, and safety, and as understanding of the underlying disease pathogenesis expands.

Specifying GC dosing, route of administration, and tapering guidelines is an important endeavor, but was beyond the scope of this project and not amenable to the RAND/UCLA methodology. However, a recent study used consensus methodology to develop an algorithm for standardized GC management in systemic JIA (72). Optimal combinations of DMARD therapies with or without therapies with a biologic agent for the scenarios above are not well understood, and it is anticipated that new data may help to clarify these treatment choices as well. Lastly, although the treatment pathways generated by these recommendations have been simplified as much as possible to facilitate their use in the clinical setting, they remain relatively complex. This complexity reflects the level of discussion and decision making by the TFP and it is anticipated that in the future, with more data available, these pathways may be simplified.

Development of treatment recommendations for children with systemic JIA and features of MAS is particularly challenging. First, there are no diagnostic criteria for MAS complicating systemic JIA, although preliminary criteria were proposed in 2005 and there is an international effort underway to develop these criteria based on expert opinion and analysis of existing patient data (73,74). Second, the etiology of MAS complicating systemic JIA is likely heterogeneous. As such, a specified stepwise treatment algorithm will not work for all patients with this disease. As more is learned about the various etiologies and pathophysiology of MAS in this population of patients, we will hopefully be able to use more targeted and efficacious therapies. The recommendation to use anakinra, calcineurin inhibitors, and GCs is certainly an important first step. However, it is anticipated that in the near future, with more data regarding treatments and a better understanding of the disease process, these recommendations may be modified.

It should be noted that these recommendations do not address the initial screening for TB prior to prescribing immunosuppressive medication, the necessity of which has been clearly established elsewhere (75). These guidelines also do not assess the method of screening, since this is addressed by the American Academy of Pediatrics (AAP) Red Book and by the Centers for Disease Control and Prevention (75,76). Currently, interferon-γ–release testing is not indicated for children ages <5 years. The AAP Red Book does not recommend repeat routine testing for children who remain at low risk while receiving immunosuppressive medication, consistent with the conclusion of the TFP for this project. If the patient history or local epidemiologic factors suggest a possible exposure, immediate and periodic skin testing or interferon-γ–release testing is recommended by the AAP.

These recommendations are distinct from the recently published Childhood Arthritis and Rheumatology Research Alliance (CARRA) systemic JIA consensus treatment plans (CTPs) (77). The CARRA treatment plans reflect the existing diverse treatment practices across North America, are based on nominal

group consensus techniques, and were developed for the purpose of conducting observational comparative effectiveness research. In contrast to these guidelines, the CTPs do not address specific disease phenotypes, and are more restricted in the medications assessed. It is anticipated that data from comparative effectiveness research based upon the CARRA CTPs will likely be very informative in future guidelines projects.

These recommendations, representing the culmination of a rigorous systematic literature review and the use of the RAND/UCLA appropriateness methodology, are an important contribution to the care of children with systemic JIA, offering recommendations to providers caring for children with this challenging disease.

ACKNOWLEDGMENTS

The authors would like to thank Janet Joyce, Amy Miller, and Regina Parker of the ACR for their guidance and administrative support. We would also like to thank the following people for their assistance with screening and abstraction of articles for the development of the Evidence Report: Drs. Abdul Al-Rasheed, Alex Aminoff, Danielle Bennett, Colleen Correll, Lauren Henderson, Patricia Hobday, Ginger Janow, Jennifer Ji Young Lee, Pai-Yue Lu, Melissa Mannion, Theresa Muskardin, Dax Rumsey, Yonit Sterba, Alysha Taxter, and Patricia Vega-Fernandez.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Drs. Ringold and Weiss had full access to all of the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception and design. Ringold, Weiss, Beukelman, DeWitt, Ilowite, Kimura, Laxer, Lovell, Nigrovic, Robinson, Vehe.

Acquisition of data. Ringold, Weiss, Beukelman, Laxer, Lovell, Nigrovic.

Analysis and interpretation of data. Ringold, Weiss, Ilowite, Kimura, Laxer, Nigrovic.

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the clinician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes, but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision, as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The American College of Rheumatology is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To develop an evidence-based guideline for the comprehensive management of osteoarthritis (OA) as a collaboration between the American College of Rheumatology (ACR) and the Arthritis Foundation, updating the 2012 ACR recommendations for the management of hand, hip, and knee OA.

Methods. We identified clinically relevant population, intervention, comparator, outcomes questions and critical outcomes in OA. A Literature Review Team performed a systematic literature review to summarize evidence supporting the benefits and harms of available educational, behavioral, psychosocial, physical, mind-body, and pharmacologic therapies for OA. Grading of Recommendations Assessment, Development and Evaluation methodology was used to rate the quality of the evidence. A Voting Panel, including rheumatologists, an internist, physical and occupational therapists, and patients, achieved consensus on the recommendations.

Results. Based on the available evidence, either strong or conditional recommendations were made for or against the approaches evaluated. Strong recommendations were made for exercise, weight loss in patients with knee and/or hip OA who are overweight or obese, self-efficacy and self-management programs, tai chi, cane use, hand orthoses for first carpometacarpal (CMC) joint OA, tibiofemoral bracing for tibiofemoral knee OA, topical nonsteroidal antiinflammatory drugs (NSAIDs) for knee OA, oral NSAIDs, and intraarticular glucocorticoid injections for knee OA. Conditional recommendations were made for balance exercises, yoga, cognitive behavioral therapy, kinesiotaping for first CMC OA, orthoses for hand joints other than the first CMC joint, patellofemoral bracing for patellofemoral knee OA, acupuncture, thermal modalities, radiofrequency ablation for knee OA, topical NSAIDs, intraarticular steroid injections and chondroitin sulfate for hand OA, topical capsaicin for knee OA, acetaminophen, duloxetine, and tramadol.

Conclusion. This guideline provides direction for clinicians and patients making treatment decisions for the management of OA. Clinicians and patients should engage in shared decision-making that accounts for patients' values, preferences, and comorbidities. These recommendations should not be used to limit or deny access to therapies.

INTRODUCTION

Osteoarthritis (OA) is the most common form of arthritis, affecting an estimated 302 million people worldwide (1–5), and is a leading cause of disability among older adults. The knees, hips, and hands are the most commonly affected appendicular joints. OA is characterized by pathology involving the whole joint, including cartilage degradation, bone remodeling, osteophyte formation, and synovial inflammation, leading to pain, stiffness, swelling, and loss of normal joint function.

As OA spans decades of a patient's life, patients with OA are likely to be treated with a number of different pharmaceutical and nonpharmaceutical interventions, often in combination. This report provides recommendations to guide patients and clinicians in choosing among the available treatments. Certain principles of management apply to all patients with OA (see Comprehensive Management of OA below and Figure 1). Some recommendations are specific to a particular joint (e.g., hip, knee, patellofemoral joint, first carpometacarpal joint [CMC]) or particular patient populations (e.g., those with erosive OA).

METHODS

This guideline, from the American College of Rheumatology (ACR) and the Arthritis Foundation (AF), follows the ACR guideline development process (https://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines), using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology to rate the quality of the available evidence and to develop the recommendations (6). ACR policy guided management of conflicts of interest and disclosures (https://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines/Osteoarthritis). A full description of the methods is presented in Supplementary Appendix 1 (on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract).

Briefly, this work involved 5 teams: 1) a Core Leadership Team that supervised and coordinated the project and drafted the clinical/population, intervention, comparator, outcomes (PICO) questions that served as the basis for the evidence report and manuscript; 2) a Literature Review Team that completed the literature screening and data abstraction and produced the Evidence Report (Supplementary Appendix 2, http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract); 3) an Expert Panel that had input into scoping and clinical/PICO question development; 4) a Patient Panel; and 5) an interprofessional Voting Panel that included rheumatologists, an internist, physical and occupational therapists, and patients (Supplementary Appendix 3, http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract).

This guideline included an initial literature review limited to English-language publications from inception of the databases to October 15, 2017, with updated searches conducted on August 1, 2018 and relevant papers included. Studies published after August 1, 2018 were not evaluated for this guideline. Supplementary Appendix 4 (http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract) shows search terms used and databases reviewed, and Supplementary Appendix 5 (http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract) highlights the study selection process. The guideline evidence base results from our own systematic review of randomized

Submitted for publication July 2, 2019; accepted in revised form October 11, 2019.

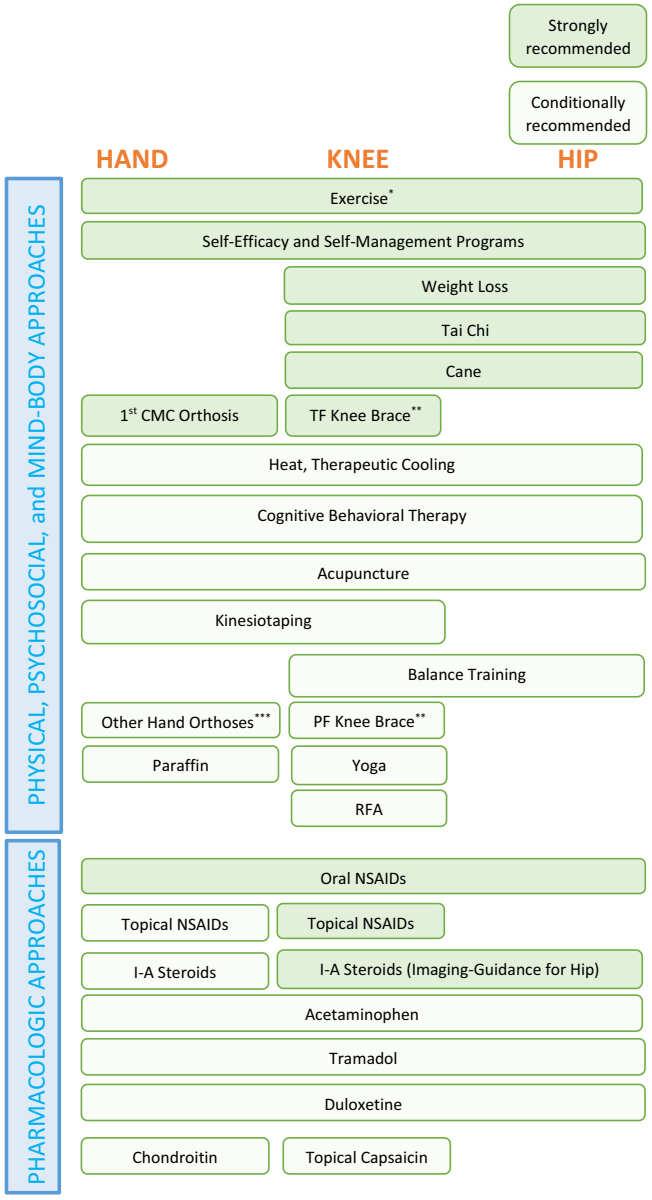

Figure 1. Recommended therapies for the management of osteoarthritis (OA). Strongly and conditionally recommended approaches to management of hand, knee, and/or hip OA are shown. No hierarchy within categories is implied in the figure, with the recognition that the various options may be used (and reused) at various times during the course of a particular patient's disease. * = Exercise for knee and hip OA could include walking, strengthening, neuromuscular training, and aquatic exercise, with no hierarchy of one over another. Exercise is associated with better outcomes when supervised. ** = Knee brace recommendations: tibiofemoral (TF) brace for TF OA (strongly recommended), patellofemoral (PF) brace for PF OA (conditionally recommended). *** = Hand orthosis recommendations: first carpometacarpal (CMC) joint neoprene or rigid orthoses for first CMC joint OA (strongly recommended), orthoses for joints of the hand other than the first CMC joint (conditionally recommended). RFA = radiofrequency ablation; NSAIDs = nonsteroidal antiinflammatory drugs; IA = intraarticular.

controlled trials (RCTs), rather than focusing on systematic reviews and meta-analyses published by others, as was done for the 2012 ACR recommendations for the use of nonpharmacologic and pharmacologic therapies in hand, hip, and knee OA (7). Systematic reviews of observational studies published by others were included if, in the opinion of the Voting Panel, they added critical information for the formulation of a recommendation: for example, related to adverse effects that may not be seen in shorter-duration RCTs. Subsequent updates of this guideline will consider studies included here and new RCTs published since completion of the literature review for the current publication.

Although RCTs are considered the gold standard for evaluation, a number of limitations of RCTs proved particularly important in the formulation of the final recommendations: possible publication bias (favoring publication of positive results), inadequate blinding, and inadequate provision of active comparators and appropriate sham alternatives. Further, short-duration RCTs cannot provide adequate prognostic information when applied to a complex disease such as OA, in which pathophysiologic processes are slowly progressive over decades.

We focused on management options that are available in the US and, for pharmacologic therapies, we additionally focused on agents that are available in pharmaceutical-grade formulations, thus eliminating most nutraceuticals. We limited our review to the English-language literature. We reviewed www.clinicaltrials.gov to identify phase 2 and 3 trials that may be far enough along to be US Food and Drug Administration (FDA)–approved and available by the time this guideline was published.

A hierarchy of outcome measures assessing pain and function in OA was developed based on the published literature (8,9). This hierarchy is detailed in Supplementary Appendix 1 (http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract).

Using GRADE, a recommendation can be either in favor of or against the proposed intervention and either strong or conditional (10,11). The strength of the recommendation is based on a 70% consensus among the Voting Panel members. Much of the evidence proved indirect (did not specifically address the PICO question as written) and of low-to-moderate quality (12,13). The Voting Panel made *strong recommendations* when it inferred compelling evidence of efficacy and that benefits clearly outweighed harms and burdens. Thus, a strong recommendation means that the Voting Panel was confident that the desirable effects of following the recommendation outweigh potential undesirable effects (or vice versa), so the course of action would apply to all or almost all patients, and only a small proportion of patients would not want to follow the recommendation.

The Voting Panel made *conditional recommendations* when the quality of the evidence proved low or very low and/

or the balance of benefits versus harms and burdens was sufficiently close that shared decision-making between the patient and the clinician would be particularly important. Conditional recommendations are those for which the majority of informed patients would choose to follow the recommended course of action, but some would not (14,15). Thus, conditional recommendations are particularly value- and preference-sensitive and always warrant a full shared decision-making approach involving a complete and clear explication of benefits, harms, and burdens in language and in a context that patients understand (16). Where recommendations are made regarding a particular approach, details and references regarding that approach can be found in the Evidence Report (Supplementary Appendix 2, http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract).

RESULTS/RECOMMENDATIONS

Comprehensive management of OA

A comprehensive plan for the management of OA in an individual patient may include educational, behavioral, psychosocial, and physical interventions, as well as topical, oral, and intraarticular medications. Recommendations assume appropriate application of physical, psychological, and/or pharmacologic therapies by an appropriate provider. Goals of management and principles for implementing those goals have broad applicability across patients. However, for some patients at some time points, a single physical, psychosocial, mind-body, or pharmacologic intervention may be adequate to control symptoms; for others, multiple interventions may be used in sequence or in combination. Which interventions and the order in which interventions are used will vary among patients. An overview of a general approach to management of OA is outlined in Figure 1 for recommended options, but no specific hierarchy of one option over another is implied other than on the basis of strength of the recommendation. Figure 2 summarizes the approaches that were not recommended.

Treatment decisions should take the personal beliefs and preferences of the patient, as well as the patient's medical status, into consideration. This guideline applies to patients with OA with no specific contraindications to the recommended therapies. However, each patient should be assessed for the presence of medical conditions, such as hypertension, cardiovascular disease, heart failure, gastrointestinal bleeding risk, chronic kidney disease, or other comorbidities, that might have an impact on their risk of side effects from certain pharmacologic agents, as well as injuries, disease severity, surgical history, and access to and availability of services (transportation, distance, ability to take time off work, cost, insurance coverage) that might have an impact on the choice of physical, psychological, and mind-body approaches. It is assumed that such an assessment

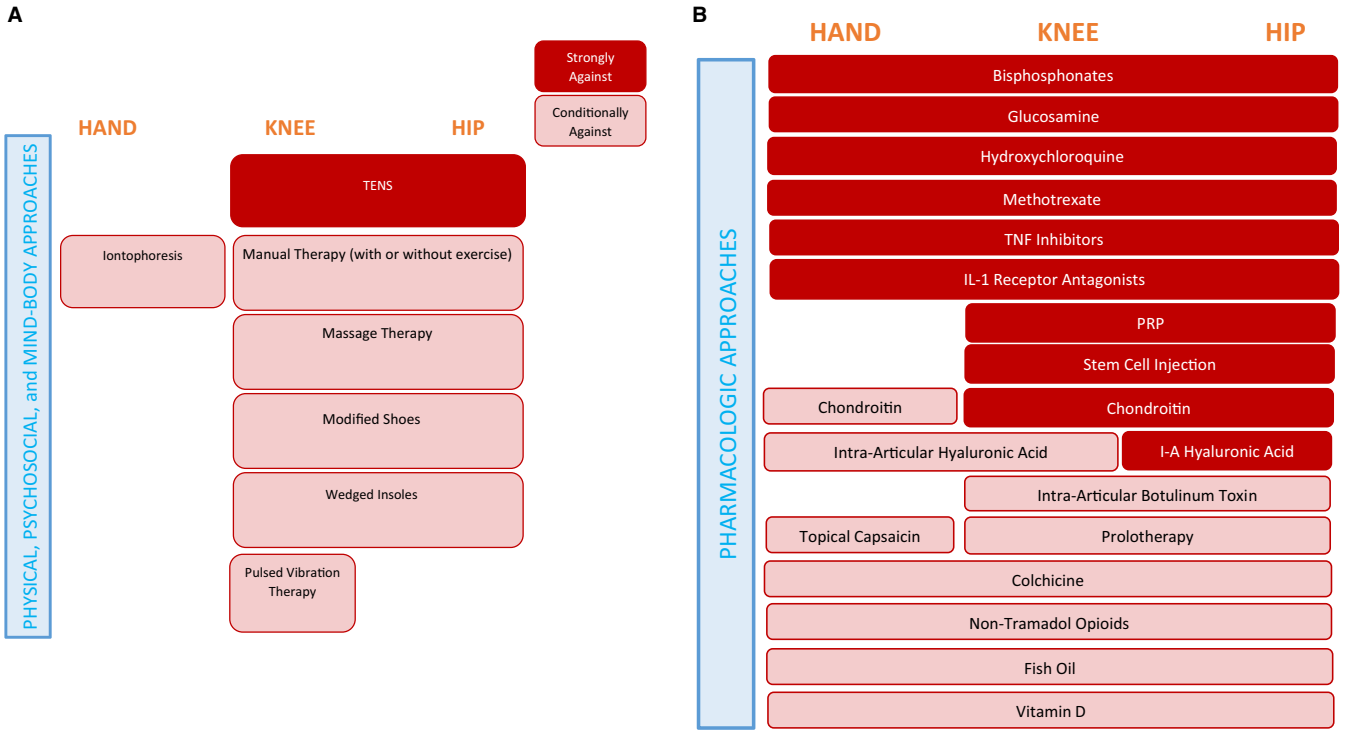

Figure 2. Therapies recommended *against* (physical, psychosocial, and mind-body approaches [**A**] and pharmacologic approaches [**B**]) in the management of hand, knee, and/or hip osteoarthritis. No hierarchy within categories is implied in the figure. TENS = transcutaneous electrical nerve stimulation; TNF = tumor necrosis factor; IL-1 = interleukin-1; PRP = platelet-rich plasma; IA = intraarticular.

will be performed prior to finalization of an individual treatment plan. When choosing among pharmacologic therapies, management should begin with treatments with the least systemic exposure or toxicity.

Patients may experience a variety of additional symptoms as a result of the pain and functional limitations arising from OA and/or comorbidities. These include mood disorders, such as depression and anxiety, altered sleep, chronic widespread pain, and impaired coping skills. The Patient Panel noted that the broader impact of OA on these comorbidities is of particular importance when choosing among treatment options and best addressed by a multimodal treatment plan, rather than one that is limited to the prescription of a single medication. Measures aimed at improving mood, reducing stress, addressing insomnia, managing weight, and enhancing fitness may improve the patient's overall well-being and OA treatment success. Indeed, interventions that have proven beneficial in the management of chronic pain may prove useful in OA (17) even when data specific to patients with OA are limited.

Unless otherwise specified, recommendations regarding physical, psychosocial, and mind-body approaches assume that the patient will be adding the intervention to usual care. For the purposes of this guideline, usual care includes the use of maximally recommended or safely tolerated doses of over-the counter oral nonsteroidal antiinflammatory drugs (NSAIDs) and/or acetaminophen, as has generally been explicitly permitted in clinical trials of nonpharmacologic interventions.

Physical, psychosocial, and mind-body approaches (Table 1)

During the GRADE analysis, clinical trials involving physical modalities and mind-body approaches were often designated as yielding low-quality evidence because blinding with regard to the active treatment was not always possible. This contributed to a preponderance of conditional recommendations for physical modalities and mind-body approaches. The delivery of instruction by physical and occupational therapists is helpful, and often essential, for the appropriate initiation and maintenance of exercise as a part of OA management. In addition to exercise, physical and occupational therapists often incorporate self-efficacy and self-management training, thermal therapies, and instruction in use of and fitting of splints and braces in their practices. Most patients with OA are likely to experience benefit from referral to physical therapy and/or occupational therapy at various times during the course of their disease.

Exercise is strongly recommended for patients with knee, hip, and/or hand OA.

Though exercise is strongly recommended for all OA patients, there is considerably more evidence for the use of exercise in the treatment of knee and hip OA than for hand OA, and the variety of exercise options studied is far greater. While patients and providers seek recommendations on the "best" exercise and the ideal dosage (duration, intensity, and frequency), current evidence

is insufficient to recommend specific exercise prescriptions. Broad recommendations suggesting one form of exercise over another are based largely on expert opinion. A substantial body of literature (see Evidence Report, Supplementary Appendix 2 [http://onlinelibrary.wiley.com/doi/10.1002/art.41142/abstract]) supports a wide range of appropriate exercise options and suggests that the vast majority of OA patients can participate in, and benefit from with regard to pain and function, some form of exercise. Exercise recommendations to patients should focus on the patient's preferences and access, both of which may be important barriers to participation. If a patient does not find a certain form of exercise acceptable or cannot afford to participate or arrange transportation to participate, he or she is not likely to get any benefit from the suggestion to pursue that exercise.

In the majority of studies that assessed the role of aerobic exercise in the management of OA, walking was the most common form of exercise evaluated, either on a treadmill or as supervised, community-based, indoor fitness walking. Other studies used supervised group cycling on stationary bicycles. Strengthening exercises have included the use of isokinetic weight machines, resistance exercise training with and without props such as elastic bands, and isometric exercise. Neuromuscular training has been developed to address muscle weakness, reduced sensorimotor control, and functional instability specifically seen with knee OA, with a series of dynamic maneuvers of increased complexity. Aquatic exercise often encompasses aspects of aerobic fitness exercises and exercises for enhancing joint range of motion, in a low-impact environment.

A specific hierarchy of these various forms of exercise could not be discerned from the literature. Patient participants on the Patient and Voting Panels raised the concern that patients who are in pain might be hesitant to participate in exercise. There is no uniformly accepted level of pain at which a patient should or should not exercise, and a common-sense approach of shared decision-making between the treating clinician and the patient regarding when to initiate an exercise program is advisable. However, clinical trials of exercise for OA include patients with pain and functional limitations due to OA, and improvements in OA-specific outcomes have been demonstrated; thus, results are likely to be generalizable to most patients with pain due to OA.

Although there is currently insufficient evidence to recommend one form of exercise over another, patients will likely benefit from advice that is as specific as possible, rather than simple encouragement to exercise. Given the wide range of evidence-based exercise interventions shown to effectively improve pain and function in OA, all patients should be encouraged to consider some form of exercise as a central part of their treatment plan. Individual preferences, access, and affordability are likely to play a role in what works best for an individual patient. Overall, exercise programs are more effective if supervised, often by physical therapists and sometimes in a class setting, rather than when performed by the individual at home. They also tend to be more effective when combined with self-efficacy and self-management interventions or weight loss programs.

Few studies have employed monitoring devices or pre- and postintervention assessment of cardiovascular or musculoskeletal fitness, so targets using these devices or assessments are not available. Future research is essential to establish specific exercise guidelines that will direct the patient and provider toward more individualized exercise prescriptions.

Balance exercises are conditionally recommended for patients with knee and/or hip OA.

Balance exercises include those that improve the ability to control and stabilize body position (American Physical Therapy Association: http://www.apta.org/BalanceFalls/). Although one might expect balance exercises to help reduce the risk of falls in patients with OA, RCTs to date have not addressed this outcome in this population, and the low quality of evidence addressing the use of balance exercises necessitates only a conditional recommendation for balance exercises.

Weight loss is strongly recommended for patients with knee and/or hip OA who are overweight or obese.

A dose-response has been noted with regard to the amount of weight loss that will result in symptom or functional improvement in patients with OA (18). A loss of ≥5% of body weight can be associated with changes in clinical and mechanistic outcomes. Furthermore, clinically important benefits continue to increase with weight loss of 5–10%, 10–20%, and >20% of body weight. The efficacy of weight loss for OA symptom management is enhanced by use of a concomitant exercise program.

Self-efficacy and self-management programs are strongly recommended for patients with knee, hip, and/or hand OA.

Although effect sizes are generally small, the benefits of participation in self-efficacy and self-management programs are consistent across studies, and risks are minimal. These programs use a multidisciplinary group–based format combining sessions on skill-building (goal-setting, problem-solving, positive thinking), education about the disease and about medication effects and side effects, joint protection measures, and fitness and exercise goals and approaches. Health educators, National Commission for Certification Services–certified fitness instructors, nurses, physical therapists, occupational therapists, physicians, and patient peers may lead the sessions, which can be held in person or online. In the studies reviewed, sessions generally occurred 3 times weekly, but varied from 2 to 6 times weekly.

Tai chi is strongly recommended for patients with knee and/or hip OA.

Tai chi is a traditional Chinese mind-body practice that combines meditation with slow, gentle, graceful movements, deep diaphragmatic breathing, and relaxation. The efficacy of tai chi may

reflect the holistic impact of this mind-body practice on strength, balance, and fall prevention, as well as on depression and self-efficacy.

Yoga is conditionally recommended for patients with knee OA.

Yoga is a mind-body practice with origins in ancient Indian philosophy and typically combines physical postures, breathing techniques, and meditation or relaxation (National Center for Complementary and Integrative Health [NCCIH]: https://nccih.nih.gov/health/yoga). Though far less well studied than tai chi, yoga may be helpful in OA through a similar blend of physical and psychosocial factors. Due to lack of data, no recommendation can be made regarding use of yoga to help manage symptoms of hip OA. Other mind-body practices could not be assessed due to insufficient evidence, as well as a lack of standard definitions of certain interventions (hypnosis, qi gong).

Cognitive behavioral therapy (CBT) is conditionally recommended for patients with knee, hip, and/or hand OA.

There is a well-established body of literature (19,20) supporting the use of CBT in chronic pain conditions, and CBT may have relevance for the management of OA. Trials have demonstrated improvement in pain, health-related quality of life, negative mood, fatigue, functional capacity, and disability in conditions other than OA. In OA, limited evidence suggests that CBT may reduce pain (21). Further research is needed to establish whether or not benefits in OA are related to alteration in mood, sleep, coping, or other factors that may co-occur with, result from, or be a part of the experience of OA (22).

Cane use is strongly recommended for patients with knee and/or hip OA in whom disease in 1 or more joints is causing a sufficiently large impact on ambulation, joint stability, or pain to warrant use of an assistive device.

Tibiofemoral knee braces are strongly recommended for patients with knee OA in whom disease in 1 or both knees is causing a sufficiently large impact on ambulation, joint stability, or pain to warrant use of an assistive device, and who are able to tolerate the associated inconvenience and burden associated with bracing.

Patellofemoral braces are conditionally recommended for patients with patellofemoral knee OA in whom disease in 1 or both knees is causing a sufficiently large impact on ambulation, joint stability, or pain to warrant use of an assistive device.

The recommendation is conditional due to the variability in results across published trials and the difficulty some patients will have in tolerating the inconvenience and burden of these braces. Optimal management with knee bracing is likely to require that clinicians are familiar with the various types of braces and where they are available and have expertise in fitting the braces. Patient Voting Panel members strongly emphasized the importance of coordination of care between primary care providers, specialists, and providers of braces.

Kinesiotaping is conditionally recommended for patients with knee and/or first CMC joint OA.

Kinesiotaping permits range of motion of the joint to which it is applied, in contrast to a brace, which maintains the joint in a fixed position. Published studies have examined various products and methods of application, and blinding with regard to use is not possible, thereby limiting the quality of the evidence.

Hand orthoses are strongly recommended for patients with first CMC joint OA.

Hand orthoses are conditionally recommended for patients with OA in other joints of the hand.

A variety of mechanical supports are available, including digital orthoses, ring splints, and rigid or neoprene orthoses, some of which are intended for specifically affected joints (e.g., first CMC joint, individual digits, wrist) and some of which support the entire hand. In addition, gloves may offer benefit by providing warmth and compression to the joints of the hand. Data are insufficient to recommend one type of orthosis over another for use in the hand. Patients considering these interventions will likely benefit from evaluation by an occupational therapist.

Modified shoes are conditionally recommended *against* in patients with knee and/or hip OA.

Modifications to shoes can be intended to alter the biomechanics of the lower extremities and the gait. While optimal footwear is likely to be of considerable importance for those with knee and/or hip OA, the available studies do not define the best type of footwear to improve specific outcomes for knee or hip OA.

Lateral and medial wedged insoles are conditionally recommended *against* in patients with knee and/or hip OA.

The currently available literature does not demonstrate clear efficacy of lateral or medial wedged insoles.

Acupuncture is conditionally recommended for patients with knee, hip, and/or hand OA.

Although a large number of trials have addressed the use of acupuncture for OA, its efficacy remains a subject of controversy. Issues related to the use of appropriate blinding, the validity of sham controls, sample size, effect size, and prior expectations have arisen with regard to this literature. Variability in the results of RCTs and meta-analyses is likely driven, in part, by differences in the type of controls and the intensity of the control

interventions used. In addition, the benefits of acupuncture result from the large contextual effect plus small differences in outcomes between "true" and "sham" acupuncture. The latter is of the same magnitude as the effect of full-dose acetaminophen versus placebo. The greatest number of positive trials with the largest effect sizes have been carried out in knee OA. Positive trials and meta-analyses have also been published in a variety of other painful conditions and have indicated that acupuncture is effective for analgesia. While the "true" magnitude of effect is difficult to discern, the risk of harm is minor, resulting in the Voting Panel providing a conditional recommendation.

Thermal interventions (locally applied heat or cold) are conditionally recommended for patients with knee, hip, and/or hand OA.

The method of delivery of thermal interventions varies considerably in published reports, including moist heat, diathermy (electrically delivered heat), ultrasound, and hot and cold packs. Studies using diathermy or ultrasound were more likely to be sham controlled than those using other heat delivery modalities. The heterogeneity of modalities and short duration of benefit for these interventions led to the conditional recommendation.

Paraffin, an additional method of heat therapy for the hands, is conditionally recommended for patients with hand OA.

Radiofrequency ablation is conditionally recommended for patients with knee OA.

A number of studies have demonstrated potential analgesic benefits with various ablation techniques but, because of the heterogeneity of techniques and controls used and lack of long-term safety data, this recommendation is conditional.

Massage therapy is conditionally recommended *against* in patients with knee and/or hip OA.

Massage therapy encompasses a number of techniques aimed at affecting muscle and other soft tissue (NCCIH: https://nccih.nih.gov/health/massage/massageintroduction.htm#hed2). Studies addressing massage have suffered from high risk of bias, have included small numbers of patients, and have not demonstrated benefit for OA-specific outcomes. Patient participants on the Patient and Voting Panels noted that some studies have shown positive outcomes and minimal risk and felt strongly that massage therapy was beneficial for symptom management (23). However, based on the available evidence regarding OA specifically, a conditional recommendation against the use of massage for reduction of OA symptoms is made, though the Voting Panel acknowledged that massage may have other benefits.

Manual therapy with exercise is conditionally recommended *against* over exercise alone in patients with knee and/or hip OA.

Manual therapy techniques may include manual lymphatic drainage, manual traction, massage, mobilization/manipulation, and passive range of motion and are always used in conjunction with exercise (http://guidetoptpractice.apta.org/content/1/SEC38.extract). A limited number of studies have addressed manual therapy added to exercise versus exercise alone in hip and knee OA. Although manual therapy can be of benefit for certain conditions, such as chronic low back pain, limited data in OA show little additional benefit over exercise alone for managing OA symptoms.

Iontophoresis is conditionally recommended *against* in patients with first CMC joint OA.

There are no published RCTs evaluating iontophoresis for OA in any anatomic location.

Pulsed vibration therapy is conditionally recommended *against* in patients with knee OA.

Few trials have addressed pulsed vibration therapy, and in the absence of adequate data, we conditionally recommend against its use.

Transcutaneous electrical stimulation (TENS) is strongly recommended *against* in patients with knee and/or hip OA.

Studies examining the use of TENS have been of low quality with small size and variable controls, making comparisons across trials difficult. Studies have demonstrated a lack of benefit for knee OA.

Pharmacologic management (Table 2)

RCTs of pharmacologic agents may be subject to a variety of limitations, including generalizability of their findings across patients. Publication bias may reduce the likelihood that negative trials will become part of the published literature. Statistically significant findings may represent benefits so small that they are not clinically important to patients. We have highlighted these considerations where relevant.

Topical NSAIDs are strongly recommended for patients with knee OA and conditionally recommended for patients with hand OA.

In keeping with the principle that medications with the least systemic exposure (i.e., local therapy) are preferable, topical NSAIDs should be considered prior to use of oral NSAIDs (24). Practical considerations (e.g., frequent hand washing) and the lack of direct evidence of efficacy in the hand lead to a conditional recommendation for use of topical NSAIDs in hand OA. In hip OA, the depth of the joint beneath the skin surface suggests that topical NSAIDs are unlikely to

Table 2. Recommendations for the pharmacologic management of osteoarthritis of the hand, knee, and hip

No recommendation

confer benefit, and thus, the Voting Panel did not examine use in hip OA.

Topical capsaicin is conditionally recommended for patients with knee OA and conditionally recommended *against* in patients with hand OA.

Topical capsaicin is conditionally recommended for treatment of knee OA due to small effect sizes and wide confidence intervals in the available literature. We conditionally recommend against the use of topical capsaicin in hand OA because of a lack of direct evidence to support use, as well as a potentially increased risk of contamination of the eye with use of topical capsaicin to treat hand OA. In hip OA, the depth of the joint beneath the skin surface suggests that topical capsaicin is unlikely to have a meaningful effect, and thus, the Voting Panel did not examine use of topical capsaicin in hip OA. Insufficient data exists to make recommendations about the use of topical lidocaine preparations in OA.

Oral NSAIDs are strongly recommended for patients with knee, hip, and/or hand OA.

Oral NSAIDs remain the mainstay of the pharmacologic management of OA, and their use is strongly recommended. A large number of trials have established their short-term efficacy. Oral NSAIDs are the initial oral medication of choice in the treatment of OA, regardless of anatomic location, and are recommended over all other available oral medications.

While this guideline did not address the relative merits of different NSAIDs, there is evidence suggesting that certain agents may have more favorable side effect profiles than others (25–27). Clinical considerations aimed at risk mitigation for the safe use of NSAIDs, such as appropriate patient selection, regular monitoring for the development of potential adverse gastrointestinal, cardiovascular, and renal side effects and potential drug interactions, were not specifically included in the GRADE process for the formulation of recommendations. Doses should be as low as possible, and NSAID treatment should be continued for as short a time as possible.

Intraarticular glucocorticoid injections are strongly recommended for patients with knee and/or hip OA and conditionally recommended for patients with hand OA.

Trials of intraarticular glucocorticoid injections have demonstrated short-term efficacy in knee OA. Intraarticular glucocorticoid injection is conditionally, rather than strongly, recommended for hand OA given the lack of evidence specific to this anatomic location. There are insufficient data to judge the choice of short-acting over long-acting preparations or the use of low rather than high doses. A recent report (28) raised the possibility that specific steroid preparations or a certain frequency of steroid injections may contribute to cartilage loss, but the Voting Panel was uncertain of the clinical significance of this finding, particularly since

change in cartilage thickness was not associated with a worsening in pain, functioning, or other radiographic features.

Ultrasound guidance for intraarticular glucocorticoid injection is strongly recommended for injection into hip joints.

When available, ultrasound guidance for steroid injection may help ensure accurate drug delivery into the joint, but is not required for knee and hand joints. However, imaging guidance for injection into hip joints is strongly recommended.

Intraarticular glucocorticoid injections versus other injections are conditionally recommended for patients with knee, hip, and/or hand OA.

In OA generally, intraarticular glucocorticoid injection is conditionally recommended over other forms of intraarticular injection, including hyaluronic acid preparations. Head-to-head comparisons are few, but the evidence for efficacy of glucocorticoid injections is of considerably higher quality than that for other agents.

Acetaminophen is conditionally recommended for patients with knee, hip, and/or hand OA.

In clinical trials, the effect sizes for acetaminophen are very small, suggesting that few of those treated experience important benefit, and meta-analysis has suggested that use of acetaminophen as monotherapy may be ineffective (29). Longer-term treatment is no better than treatment with placebo for most individuals. Members of the Patient Panel noted that, for most individuals, acetaminophen is ineffective. For those with limited pharmacologic options due to intolerance of or contraindications to the use of NSAIDs, acetaminophen may be appropriate for short-term and episodic use. Regular monitoring for hepatotoxicity is required for patients who receive acetaminophen on a regular basis, particularly at the recommended maximum dosage of 3 gm daily in divided doses.

Duloxetine is conditionally recommended for patients with knee, hip, and/or hand OA.

While studied primarily in the knee, the effects of duloxetine may plausibly be expected to be similar for OA of the hip or hand. While a variety of centrally acting agents (e.g., pregabalin, gabapentin, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, and tricyclic antidepressants) have been used in the management of chronic pain, only duloxetine has adequate evidence on which to base recommendations for use in OA. However, in considering all the ways in which OA may be affecting an individual patient, shared decision-making between the physician and patient may include consideration of any of these agents. Considering the utility of these agents in pain management generally, their use may be an appropriate target of future investigations specific to OA. Evidence suggests that duloxetine has efficacy in the treatment of OA when used alone or in combination with NSAIDs; however, there are issues regarding tolerability and side effects. No recommendations were made for the other centrally acting agents due to lack of direct studies of relevance in OA.

Tramadol is conditionally recommended for patients with knee, hip, and/or OA.

Recent work has highlighted the very modest level of beneficial effects in the long-term (3 months to 1 year) management of non-cancer pain with opioids (30). Nonetheless, there are circumstances in which tramadol or other opioids may be appropriate in the treatment of OA, including when patients may have contraindications to NSAIDs, find other therapies ineffective, or have no available surgical options. Patient Panel input demonstrated a high level of understanding concerning addiction potential, but also included an appreciation for the role of these agents when other pharmacologic and physical options have been ineffective. However, RCT evidence addressing the use of tramadol and other opioids for periods longer than 1 year is not available. Clinical trials have demonstrated some symptomatic efficacy, though concerns regarding potential adverse effects remain. If an opioid is being considered, tramadol is conditionally recommended over non-tramadol opioids.

Non-tramadol opioids are conditionally recommended *against* in patients with knee, hand, and/or hip OA with the recognition that they may be used under certain circumstances, particularly when alternatives have been exhausted.

As noted above, evidence suggests very modest benefits of long-term opioid therapy and a high risk of toxicity and dependence. Use of the lowest possible doses for the shortest possible length of time is prudent, particularly since a recent systematic review and meta-analysis suggests that less pain relief occurs during longer trials in the treatment of non-cancer chronic pain (30).

Colchicine is conditionally recommended *against* in patients with knee, hip, and/or hand OA.

Two very small studies have suggested analgesic benefit of colchicine in OA, but the quality of the data was low. In addition, potential adverse effects, as well as drug interactions, may occur with use of colchicine.

Fish oil is conditionally recommended *against* in patients with knee, hip, and/or hand OA.

Fish oil is the most commonly used dietary supplement in the US (31). Despite its popularity, only 1 published trial has addressed its potential role in OA. This study failed to show efficacy of a higher dose of fish oil over a lower dose.

Vitamin D is conditionally recommended *against* in patients with knee, hip, and/or hand OA.

A number of trials in OA demonstrated small effect sizes with vitamin D treatment, while others have shown no benefit and pooling data across studies yielded null results. In addition, limited

and questionable health benefits from vitamin D supplementation have been suggested in other contexts (32,33).

Bisphosphonates are strongly recommended *against* in patients with knee, hip, and/or hand OA.

Though a single small study of an oral bisphosphonate suggested a potential analgesic benefit in OA, the preponderance of data shows no improvement in pain or functional outcomes.

Glucosamine is strongly recommended *against* in patients with knee, hip, and/or hand OA.

Pharmaceutical-grade preparations of glucosamine are available and have been studied in multiple trials. However, discrepancies in efficacy reported in studies that were industry sponsored as opposed to publicly funded have raised serious concerns about publication bias (34,35). In addition, there is a lack of a clear biologic understanding of how efficacy would vary with the type of salt studied. The data that were deemed to have the lowest risk of bias fail to show any important benefits over placebo. These recommendations represent a change from the prior conditional recommendation against the use of glucosamine. The weight of the evidence indicates a lack of efficacy and large placebo effects. Nonetheless, glucosamine remains among the most commonly used dietary supplements in the US (31), and clinicians should be aware that many patients perceive that glucosamine is efficacious. Patients also often perceive that different glucosamine formulas are associated with different degrees of efficacy and seek advice on brands and manufacturers. The potential toxicity of glucosamine is low, though some patients exposed to glucosamine may show elevations in serum glucose levels (36).

Chondroitin sulfate is strongly recommended *against* in patients with knee and/or hip OA as are combination products that include glucosamine and chondroitin sulfate, but is conditionally recommended for patients with hand OA.

A single trial suggested analgesic efficacy of chondroitin sulfate, without evidence of harm, in hand OA.

Hydroxychloroquine is strongly recommended *against* in patients with knee, hip, and/or hand OA.

Well-designed RCTs of hydroxychloroquine, conducted in the subset of patients with erosive hand OA, have demonstrated no efficacy.

Methotrexate is strongly recommended *against* in patients with knee, hip, and/or hand OA.

Well-designed RCTs of methotrexate, conducted in the subset of patients with erosive hand OA, have demonstrated no efficacy.

Intraarticular hyaluronic acid injections are conditionally recommended *against* in patients with knee and/or first CMC joint OA and strongly recommended *against* in patients with hip OA.

In prior systematic reviews, apparent benefits of hyaluronic acid injections in OA have been reported. These reviews have not, however, taken into account the risk of bias of the individual primary studies. Our review showed that benefit was restricted to the studies with higher risk of bias: when limited to trials with low risk of bias, meta-analysis has shown that the effect size of hyaluronic acid injections compared to saline injections approaches zero (37). The finding that best evidence fails to establish a benefit, and that harm may be associated with these injections, motivated the recommendation against use of this treatment.

Many providers want the option of using hyaluronic acid injections when glucocorticoid injections or other interventions fail to adequately control local joint symptoms. In clinical practice, the choice to use hyaluronic acid injections in the knee OA patient who has had an inadequate response to nonpharmacologic therapies, topical and oral NSAIDs, and intraarticular steroids may be viewed more favorably than offering no intervention, particularly given the impact of the contextual effects of intraarticular hyaluronic acid injections (38). The conditional recommendation against is consistent with the use of hyaluronic acid injections, in the context of shared decision-making that recognizes the limited evidence of benefit of this treatment, when other alternatives have been exhausted or failed to provide satisfactory benefit. The conditional recommendation against is not intended to influence insurance coverage decisions.

In contrast, the evidence of lack of benefit is of higher quality with respect to hyaluronic acid injection in the hip. We therefore strongly recommend against hyaluronic acid injections in hip OA.

Intraarticular botulinum toxin injections are conditionally recommended *against* in patients with knee and/or hip OA.

The small number of trials of intraarticular botulinum toxin treatment in knee or hip OA suggest a lack of efficacy. This treatment has not been evaluated in hand OA and, therefore, no recommendation is made with regard to OA of the hand.

Prolotherapy is conditionally recommended *against* in patients with knee and/or hip OA.

A limited number of trials involving a small number of participants have shown small effect sizes of prolotherapy in knee or hip OA. However, injection schedules, injection sites, and comparators have varied substantially between trials. This treatment has not been evaluated in hand OA and, therefore, no recommendation is made with regard to OA of the hand.

Platelet-rich plasma treatment is strongly recommended *against* in patients with knee and/or hip OA.

In contrast to intraarticular therapies discussed above, there is concern regarding the heterogeneity and lack of standardization in available preparations of platelet-rich plasma, as well as techniques used, making it difficult to identify exactly what is being injected. This treatment has not been evaluated in hand OA and, therefore, no recommendation is made with regard to OA of the hand.

Stem cell injections are strongly recommended *against* in patients with knee and/or hip OA.

There is concern regarding the heterogeneity and lack of standardization in available preparations of stem cell injections, as well as techniques used. This treatment has not been evaluated in hand OA and, therefore, no recommendation is made with regard to OA of the hand.

Tumor necrosis factor inhibitors and interleukin-1 receptor antagonists are strongly recommended *against* in patients with knee, hip, and/or hand OA.

Tumor necrosis factor inhibitors and interleukin-1 receptor antagonists have been studied in trials using both subcutaneous and intraarticular routes of administration. Efficacy has not been demonstrated, including in erosive hand OA. Therefore, given their known risks of toxicity, we strongly recommended against their use for any form of OA.

Initial observations addressing the use of anti–nerve growth factor (anti-NGF) agents suggest that significant analgesic benefits may occur but that incompletely explained important safety issues may arise. A small subset of patients treated with these agents had rapid joint destruction leading to early joint replacement. The FDA temporarily halted clinical trials of anti-NGF as a result, but trials have since resumed, with ongoing collection of longer-term efficacy and safety data. As none of these agents were approved for use by the FDA and the longer-term data were not available at the time of the literature review and Voting Panel meeting, we are unable to make recommendations regarding the use of anti-NGF therapy.

DISCUSSION

These 2019 ACR/AF recommendations for the management of OA are based on the best available evidence of benefit, safety, and tolerability of physical, educational, behavioral, psychosocial, mind-body, and pharmacologic interventions, as well as the consensus judgment of clinical experts. The GRADE approach used provided a comprehensive, explicit, and transparent methodology for developing recommendations for OA management. The choice of any single or group of interventions may vary over the course of the disease or with patient and provider preferences, and is optimally arrived at through shared decision-making.

The Voting Panel made strong recommendations for patients to participate in a regular, ongoing exercise program. The literature provides support for choice from a broad menu of exercises for patients with OA. The effectiveness of an exercise program is enhanced when patient preferences and access to exercise programs are considered, as well as when they are supervised or coupled with self-efficacy, self-management, and weight loss programs. Strong recommendations were also made for weight loss in patients with knee and/or hip OA who are overweight or obese, self-efficacy and self-management programs, tai chi, cane use, first CMC joint orthoses, tibiofemoral bracing, topical NSAIDs for knee OA and oral NSAIDs for hand, knee, and/or hip OA, and intraarticular glucocorticoid injections for knee and/or hip OA. The Voting Panel made conditional recommendations for balance exercises, yoga, CBT, kinesiotaping, orthoses for hand joints other than the first CMC, patellofemoral bracing, acupuncture, thermal modalities, radiofrequency ablation, topical NSAIDs, intraarticular steroid injections and chondroitin sulfate for hand OA, topical capsaicin for knee OA, acetaminophen, duloxetine, and tramadol. The recommendations provide an array of options for a comprehensive approach for optimal management of OA encompassing the use of educational, physical, behavioral, psychosocial, mind-body, and pharmacologic interventions. The availability, accessibility, and affordability of some of these interventions vary, but in many communities the AF, as well as local hospitals and other health-related agencies, offer free self-efficacy and self-management programs.

For some patients with more limited disease in whom medication is required, topical NSAIDs represent an appropriate first choice. For others, particularly with hip OA or polyarticular involvement, oral NSAIDs are more appropriate. The appropriate use of other oral agents, particularly acetaminophen and opioids, will continue to evolve (39–41).

Despite the many options available, some patients may continue to experience inadequate symptom control; others will experience adverse effects from the available interventions. Clinicians treating patients in these circumstances should choose interventions with a low risk of harm, but both clinicians and patients may be dissatisfied with the options and unsure of how to choose among them. There are controversies in interpretation of the evidence, particularly with regard to the use of glucosamine and chondroitin, acupuncture, and intraarticular hyaluronic acid injections. Nonetheless, the process of updating treatment guidelines permits scrutiny of the state of the literature and identification of critical gaps in our knowledge about best practices. Further, it highlights the need for ongoing, appropriately funded, high-quality clinical research, as well as development of new treatment modalities, to address the human and economic impact of the most common form of arthritis.

No effective disease-modifying agents for OA have yet been identified though phase 2 and 3 trials are underway, and, for the time being, preventive strategies focus on weight management and injury prevention. Development of more effective therapies that

permit a sophisticated and individualized approach to the patient with OA await the outcome of future investigation. Important directions for research include gaining a more comprehensive understanding of the optimal types of exercises and the modifications that should be used based on disease location and severity, study of the intensity of exercise that would be optimal for a given individual (https://health.gov/paguidelines/second-edition/report.aspx), defining optimal footwear for patients with knee and hip OA and understanding the interaction between footwear and exercise, conducting rigorous RCTs for physical modality options in hand OA, assessing a broader array of outcomes, including fall prevention, assessing optimal use of oral, topical, and injectable agents alone and in combination, obtaining a better understanding of the role of integrative medicine, including massage, herbal products, medical marijuana, and additional mind-body interventions, and exploring agents with novel mechanisms of action for prevention and treatment.

In conclusion, optimal management requires a comprehensive, multimodal approach to treating patients with hand, hip, and/or knee OA offered in the context of shared decision-making with patients, to choose the safest and most effective treatment possible. A large research agenda remains to be addressed, with a need for more options with greater efficacy for the millions of people worldwide with osteoarthritis.

Addendum. Therapies that were approved after the original systematic literature review are not included in these recommendations.

ACKNOWLEDGMENTS

We thank Nancy Baker, ScD, MPH, OTR/l, Yvonne Golightly, PT, MS, PhD, Thomas Schnitzer, MD, PhD, and ChenChen Wang, MD, MSc for serving (along with authors Joel Block, MD, Leigh Callahan, PhD, Carole Dodge, OT, CHT, David Felson, MD, MPH, William F. Harvey, MD, MSc, Edward Herzig, MD, Marc C. Hochberg, MD, MPH, Sharon L. Kolasinski, MD, C. Kent Kwoh, MD, Amanda E. Nelson, MD, Tuhina Neogi, MD, PhD, Carol Oatis, PT, PhD, Jonathan Samuels, MD, Daniel White, PT, ScD, and Barton Wise, MD, PhD) on the Expert Panel. We thank Suzanne Schrandt, Angie Botto-van Bemden, and Jaffe Marie with the Arthritis Foundation for their involvement throughout the guideline development process. We thank the patients who (along with author Kathleen Gellar) participated in the Patient Panel meeting: Cindy Copenhaver, LMT, Donna Dernier, Fletcher Johnson, Nancy J. Maier, Travis Salmon, Elise Sargent, and Linda Walls. We thank the ACR staff, including Regina Parker for assistance in organizing the face-to-face meeting and coordinating the administrative aspects of the project and Robin Lane for assistance in manuscript preparation. We thank Janet Waters for help in developing the literature search strategy and performing the literature search and updates, and Janet Joyce for peer-reviewing the literature search strategy.

American College of Rheumatology 2012 Recommendations for the Use of Nonpharmacologic and Pharmacologic Therapies in Osteoarthritis of the Hand, Hip, and Knee

MARC C. HOCHBERG,[1] ROY D. ALTMAN,[2] KARINE TOUPIN APRIL,[3] MARIA BENKHALTI,[3] GORDON GUYATT,[4] JESSIE McGOWAN,[3] TANVEER TOWHEED,[5] VIVIAN WELCH,[3] GEORGE WELLS,[3] AND PETER TUGWELL[3]

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for particular patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to these guidelines and recommendations to be voluntary, with the ultimate determination regarding their application to be made by the physician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed or endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice.

The American College of Rheumatology is an independent, professional, medical and scientific society which does not guarantee, warrant, or endorse any commercial product or service.

Objective. **To update the American College of Rheumatology (ACR) 2000 recommendations for hip and knee osteoarthritis (OA) and develop new recommendations for hand OA.**

Methods. **A list of pharmacologic and nonpharmacologic modalities commonly used to manage knee, hip, and hand OA as well as clinical scenarios representing patients with symptomatic hand, hip, and knee OA were generated. Systematic evidence-based literature reviews were conducted by a working group at the Institute of Population Health, University of Ottawa, and updated by ACR staff to include additions to bibliographic databases through December 31, 2010. The Grading of Recommendations Assessment, Development and Evaluation approach, a formal process to rate scientific evidence and to develop recommendations that are as evidence based as possible, was used by a Technical Expert Panel comprised of various stakeholders to formulate the recommendations for the use of nonpharmacologic and pharmacologic modalities for OA of the hand, hip, and knee.**

Results. **Both "strong" and "conditional" recommendations were made for OA management. Modalities conditionally recommended for the management of hand OA include instruction in joint protection techniques, provision of assistive devices, use of thermal modalities and trapeziometacarpal joint splints, and use of oral and topical nonsteroidal antiinflammatory drugs (NSAIDs), tramadol, and topical capsaicin. Nonpharmacologic modalities strongly recommended for the management of knee OA were aerobic, aquatic, and/or resistance exercises as well as weight loss for overweight patients. Nonpharmacologic modalities conditionally recommended for knee OA included medial wedge insoles for valgus knee OA, subtalar strapped lateral insoles for varus knee OA, medially directed patellar taping, manual therapy, walking aids, thermal agents, tai chi, self-management programs, and psychosocial interventions. Pharmacologic modalities conditionally recommended for the initial management of patients with knee OA included acetaminophen, oral and topical NSAIDs, tramadol, and intraarticular corticosteroid injections; intraarticular hyaluronate injections, duloxetine, and opioids were conditionally recommended in patients who had an inadequate response to initial therapy. Opioid analgesics were strongly recommended in patients who were either not willing to undergo or had contraindications for total joint arthroplasty after having failed medical therapy. Recommendations for hip OA were similar to those for the management of knee OA.**

Conclusion. **These recommendations are based on the consensus judgment of clinical experts from a wide range of disciplines, informed by available evidence, balancing the benefits and harms of both nonpharmacologic and pharmacologic modalities, and incorporating their preferences and values. It is hoped that these recommendations will be utilized by health care providers involved in the management of patients with OA.**

INTRODUCTION

Many patients with a clinical diagnosis of osteoarthritis (OA) are treated with a combination of nonpharmacologic and pharmacologic modalities (1). The American College of Rheumatology (ACR) last published recommendations for the management of hip and knee OA in 2000 (2), with

[1]Marc C. Hochberg, MD, MPH: University of Maryland School of Medicine, Baltimore; [2]Roy D. Altman, MD: David Geffen School of Medicine, University of California, Los Angeles; [3]Karine Toupin April, OT, PhD, Maria Benkhalti, MSc, Jessie McGowan, PhD, Vivian Welch, MSc, George Wells, MD, Peter Tugwell, MD, MSc:University of Ottawa School of Medicine, Ottawa, Ontario, Canada; [4]Gordon Guyatt, MD: McMaster University School of Medicine, Hamilton, Ontario, Canada; [5]Tanveer Towheed, MD, MSc: Queen's University School of Medicine, Kingston, Ontario, Canada.

an addendum posted on the ACR web site in February 2005 (3). Since 2000, other professional societies have published recommendations for the management of hand, hip, and knee OA, including those developed by the European League Against Rheumatism (EULAR) (4–6), the Osteoarthritis Research Society International (OARSI) (7), and the American Academy of Orthopaedic Surgeons (AAOS) (8).

Past ACR recommendations for the management of hip and knee OA were derived by a small group using an informal consensus approach following an extensive literature review. Since then, the methodology used to develop clinical practice guidelines has matured with the use of systematic literature reviews and the implementation of the Delphi method for development of consensus agreement on propositions (4–7) or the RAND/University of California, Los Angeles Appropriateness Method for determining when the use of certain therapeutic modalities is appropriate in a given clinical scenario (9). The current recommendations were developed using the Grades of Recommendation Assessment, Development and Evaluation (GRADE) approach, a formal process to develop recommendations that are as evidence based as possible. The GRADE approach has been adopted by the World Health Organization, the Cochrane Collaboration, the Agency for Healthcare Research and Quality (AHRQ) (10–14), and numerous professional organizations including, among others, the American College of Physicians and, most recently, the ACR.

Since 2000, new therapies for OA and additional information on the safety and tolerability of existing therapies for OA have become available and, as noted above, the methodology for developing clinical practice guidelines has evolved. These factors combined to contribute to the decision of the ACR to revise and update recommendations for the management of OA of the hip and knee as well as create new recommendations for the management of OA of the hand. Applying these recommendations in clinical practice requires individualized assessment of the patient and consideration of the values and judgments of both the practitioner and the patient. The recommendations provided here are not intended to be used in a "cookbook" fashion, but rather to provide guidance based on clinical evidence and expert panel input. Unlike previous ACR recommendations for the management of OA, these recommendations do not recommend the sequence of subsequent interventions for those failing to have an adequate response to recommended initial therapies, as there are few, if any, high-quality studies that were designed to examine the benefit and safety of specific modalities under such assumptions. Although disseminated under the aegis of the ACR, we hope that these recommendations will have relevance to practitioners throughout the world. We specifically did not make recommendations regarding the use of pharmacologic agents that are not approved in the US and Canada, however, or regarding the use of surgical interventions, as this was beyond the scope of the charge to the committee.

Dr. Hochberg has received consultant fees (less than $10,000 each) from Abbott Laboratories, Amgen, AstraZeneca, Bayer Health Care, Bioiberica, Bristol-Myers Squibb, CombinatoRx, Covidien, Eli Lilly, Genentech, GlaxoSmithKline, Hoffman-La Roche, Merck, Merck Serono International, NicOx, Novartis, Pfizer, Pozen, Rand Corporation, Sanofi-Aventis, Smith & Nephew, Stryker Biotech, TransPharma Medical, and UCB, receives research support from the NIH, serves as a member/chair of the data safety monitoring boards for the National Eye Institute and Novartis, and serves on the medical advisory board for and owns stock in Theralogix. Dr. Altman has received consultant fees, speaking fees, and/or honoraria (less than $10,000 each) from Ferring, Rotta, Endo, Novartis, Lilly, and Smith & Nephew. Dr. Towheed has received speaking fees from and/or serves on the advisory board for Amgen, Novartis, Bristol-Myers Squibb, Hoffman-La Roche, and Schering (less than $10,000 each). Submitted for publication April 1, 2010; accepted in revised form December 23, 2011.

MATERIALS AND METHODS

Initial systematic literature review. Systematic literature searches were conducted by a working group at the University of Ottawa, which also organized the summary evidence profiles and supporting documents. Systematic literature searches were performed for more than 50 different nonpharmacologic and pharmacologic modalities that were previously identified by separate expert panels (4–7); note that tramadol was considered separately from opioid analgesics because the central analgesic effect of tramadol is thought to be mediated not only by a weak opioid receptor agonist effect but also through modulation of serotonin and norepinephrine levels. Literature searches were not performed for medications that are not commercially available in the US and Canada. The initial searches were conducted in Medline (1950–2009), Embase (1980–2009), and The Cochrane Library (issue 3, 2009) by applying database subject headings and relevant keywords (see Supplementary Appendix A for the search strategy employed for exercise, available in the online version of this article at http://onlinelibrary.wiley.com/journal/10.1002/(ISSN)2151-4658). Published search filters were modified and used to limit the search to specific high-quality study designs (15–17). The initial searches for pharmacologic modalities were conducted during the third and fourth quarters of 2008, while those for the nonpharmacologic modalities were conducted during the second and third quarters of 2009.

The goal of the literature search was to identify the most current systematic review(s) and meta-analysis(es) that would provide reliable estimates of benefits of the inter-

vention for the prespecified clinically relevant outcomes of pain and function as well as providing data on safety of the intervention; clinically relevant safety outcomes differed by type of intervention. If no systematic review or meta-analysis was available, the search results were screened for randomized controlled trials (RCTs). If more than 1 systematic review or RCT was identified for the modality and outcomes of interest, the quality of the systematic review or RCT was assessed in order to select the best-quality evidence. Observational studies on safety of interventions were included if there were no RCTs. Data from the Food and Drug Administration (FDA) Adverse Event Reporting System and unpublished data from product manufacturers or investigators were not solicited, as adequate denominator populations are often not available to allow the calculation of numbers needed to harm.

Forming the Technical Expert Panel (TEP) and developing clinical scenarios. While the initial literature review was being completed, a TEP was convened (members of the TEP are shown in Appendix A). The TEP included nationally recognized academic and practicing rheumatologists, primary care physicians, physiatrists, geriatricians, orthopedic surgeons, and occupational and physical therapists. The TEP was asked initially to develop a series of clinical scenarios representing patients with hand, hip, or knee OA who presented for management decisions. The scenarios included a base case of a patient with symptomatic hand, hip, or knee OA; clinical variations of the base case scenario depended on specific joint groups involved for hand OA and the lack of a satisfactory response and/or the presence of comorbidities for hip and knee OA. The scenarios were collated and then submitted to the ACR Board of Directors for review.

Recommendation development. Once the literature review was completed, the TEP was asked to evaluate the evidence and formulate recommendations for OA treatment in the situations outlined in the clinical scenarios. First, the TEP was provided with summaries of the best available evidence for all interventions, including evidence profiles for each intervention for the prespecified clinically important outcomes, which provided summary data on the benefits and safety of each modality. These summaries also included, for each modality examined, the percentage of patients who clinically improved in both control and treatment groups, estimated effect size, number needed to treat, number needed to harm, and a complete quality assessment of the evidence. In addition, the TEP received the final set of clinical scenarios; instructions on the use of the GRADE process (10–13); the ACR White Paper on the use of nonsteroidal antiinflammatory drugs (NSAIDs) (18); AHRQ reports on the use of nonopioid analgesics for OA (19) and treatment of primary and secondary knee OA (20); the EULAR recommendations for the management of OA of the hand, hip, and knee (4–6); the AAOS recommendations for the management of knee OA (8); the OARSI recommendations for the management of OA of the hip and knee (7); the American Heart Association Scientific Statement on the use of NSAIDs (21); and the American College of Cardiology Foundation consensus recommendations on reducing the risk of gastrointestinal (GI) adverse events in patients using antiplatelet and NSAID therapy (22). The TEP also considered drug-specific indications, contraindications, and warnings from product information labels from the US FDA.

Next, using a 5-point Likert scale, panelists were asked to use the evidence reports to make a recommendation for each pharmacologic modality as applied to each clinical scenario; nonpharmacologic modalities were evaluated for the base cases of hand, hip, and knee OA, as well as hand OA with involvement of the trapeziometacarpal joint. The scale provided to panelists included the following choices: strong recommendation to use, weak (or conditional) recommendation to use, no recommendation, weak (or conditional) recommendation not to use, and strong recommendation not to use. The strength of a recommendation reflects the quality of the evidence supporting the use of the modality as well as the extent to which one can be confident that desirable effects (i.e., benefits) of an intervention outweigh undesirable effects (i.e., harms). Strong recommendations mean that most informed patients would choose the recommended management and that clinicians can structure their interactions with patients accordingly. Conditional recommendations mean that the majority of informed patients would choose the recommended management but many would not, so clinicians must ensure that patients' care is in keeping with their values and preferences. Based on this initial TEP member feedback, an initial set of recommendations was drafted.

Initial voting was done privately with votes submitted electronically using Excel spreadsheets (Microsoft). The TEP met in person in December 2008 to complete the pharmacologic recommendations for hand, hip, and knee OA and the nonpharmacologic recommendations for hand OA. If consensus was not achieved with private voting, further discussion of the modality was conducted at the meeting with open voting and group discussion until consensus was achieved. Subsequently, the TEP met by conference call in September 2009 to complete the nonpharmacologic recommendations for hip and knee OA. Prior to the conference call, the TEP members were provided with summary data on the benefits and safety of each nonpharmacologic modality reviewed. Again, initial voting was done privately with votes submitted electronically using Excel spreadsheets. If consensus was not achieved with private voting, further discussion of the modality was conducted at the meeting with open voting and group discussion until consensus was achieved. Throughout the voting process, if one or more members of the TEP reported a conflict of interest concerning any specific modality, they were encouraged to recuse themselves from the discussion and voting on that modality.

The summary data from the systematic literature review that were provided to the TEP before its meetings are available as supplementary files in the online version of this article at http://onlinelibrary.wiley.com/journal/10.1002/(ISSN)2151-4658. These data include not only the citations for the most relevant systematic reviews and/or randomized clinical trials and how to interpret them (in the OA guideline development process document), but also the summary of findings tables indicating the efficacy and safety/tolerability of pharmacologic modalities for hip and knee OA, duloxetine, nonpharmacologic modalities

for hip and knee OA, and updated tai chi. In addition, the top-line citations for each treatment modality that were used for the development of the summary of findings tables are included in Supplementary Appendix B (available in the online version of this article at http://onlinelibrary.wiley.com/journal/10.1002/(ISSN)2151-4658).

The final set of recommendations was drafted after discussion of the evidence at each TEP meeting. Consensus was defined as 75% or more of the members of the TEP voting to either strongly or conditionally recommend using a modality, either strongly or conditionally recommend not using a modality, or choosing not to make a recommendation on the use of a modality (23). A strong recommendation for using a modality required high-quality evidence and evidence of a large gradient of difference between desirable and undesirable effects of the treatment (i.e., benefits compared to harms). A conditional recommendation for using a modality was based on absence of high-quality evidence and/or evidence of only a small gradient of difference between desirable and undesirable effects of the treatment. In addition, when there was more uncertainty and/or variability in the values and preferences of the TEP members for a specific modality, this more likely resulted in a conditional recommendation. The lack of data from appropriate RCTs resulted in either not making a recommendation or making a recommendation not to use a modality, depending on the harms of the modality in other conditions and/or the values and preferences of TEP members. The recommendations of the TEP focus on the initiation of treatments for OA of the hand, hip, and knee. Costs of care were not considered in formulating these recommendations.

Updating the literature review and finalizing the recommendations. The initial literature searches were updated during the first quarter of 2011 with a cutoff date of December 31, 2010 by the ACR staff using the identical methodology and search filters as in the original searches. The results of the updated literature search of pharmacologic agents were reviewed by physician members of the project's Steering Committee (RDA, MCH, TT, PT) to identify studies that might provide information on new treatments or new information on the efficacy or safety/tolerability of existing treatments. The results of the updated literature search for nonpharmacologic modalities were reviewed by the rheumatology health professionals who were members of a TEP to identify studies that might provide new information on the efficacy or safety/tolerability of existing modalities. Selected key articles that were used to generate the evidence profiles for each of the nonpharmacologic and pharmacologic modalities are listed in Supplementary Appendix B (available in the online version of this article at http://onlinelibrary.wiley.com/journal/10.1002/(ISSN)2151-4658).

In the second quarter of 2011, the TEP reviewed the information obtained from the updated literature search and voted electronically on the need for making any changes in the original recommendations as well as providing recommendations for any new therapeutic modalities. Conference calls were conducted in order to reach consensus, as necessary. These updated votes are included in the recommendations in this manuscript.

ACR peer review of recommendations. Following manuscript development, a draft was submitted to the ACR Guideline Subcommittee, ACR Quality of Care Committee, and ACR Board of Directors for their comments and votes in regard to approval. These comments were incorporated into the final recommendations to the extent possible.

RESULTS

Hand OA. *Base case.* An adult with symptomatic hand OA without cardiovascular comorbidities, current or past upper GI problems, or chronic kidney disease presents to her primary care provider for treatment. She has pain in several finger joints for several months. Over-the-counter (OTC) acetaminophen at dosages up to 3 gm/day was of minimal value. Radiographs revealed osteophytes at several distal and proximal interphalangeal joints with joint space narrowing but no erosions.

The evidence base for hand OA was developed in collaboration with one of the authors (TT); this report has subsequently been published in part (24). There were relatively few high-quality RCTs of interventions for hand OA published in the peer-reviewed literature. Therefore, there were no strong recommendations made by the TEP for this indication. There are, however, several conditional recommendations that are discussed in the following sections.

Nonpharmacologic modalities. The TEP conditionally recommends that all patients with hand OA should be evaluated by a health professional, either their primary care provider or an occupational or physical therapist, for their ability to perform activities of daily living and receive assistive devices as necessary, instruction in joint protection techniques, and the use of thermal agents for relief of pain and stiffness (Table 1). The TEP conditionally recommends that patients with OA involving the trapeziometacarpal joint should be provided with splints, as they may benefit from this device.

Pharmacologic modalities. The TEP conditionally recommends that patients with hand OA should be treated

Table 1. Nonpharmacologic recommendations for the management of hand OA*

We conditionally recommend that health professionals should do the following:
Evaluate the ability to perform activities of daily living (ADLs)
Instruct in joint protection techniques
Provide assistive devices, as needed, to help patients perform ADLs
Instruct in use of thermal modalities
Provide splints for patients with trapeziometacarpal joint OA

* No strong recommendations were made for the nonpharmacologic management of hand osteoarthritis (OA). The evidence supporting these interventions demonstrated only a small to moderate effect size (see supplementary bibliography for hand OA in Supplementary Appendix B, available in the online version of this article at http://onlinelibrary.wiley.com/journal/10.1002/(ISSN)2151-4658).

Table 2. Pharmacologic recommendations for the initial management of hand OA*

We conditionally recommend that health professionals should use one or more of the following:
Topical capsaicin
Topical NSAIDs, including trolamine salicylate
Oral NSAIDs, including COX-2 selective inhibitors
Tramadol
We conditionally recommend that health professionals should not use the following:
Intraarticular therapies
Opioid analgesics
We conditionally recommend that persons age ≥75 years should use topical rather than oral NSAIDs. In persons age <75 years, the TEP expressed no preference for using topical rather than oral NSAIDs.

* No strong recommendations were made for the pharmacologic management of hand osteoarthritis (OA). For patients who have an inadequate response to initial pharmacologic management, please see the Results for alternative strategies. NSAIDs = nonsteroidal antiinflammatory drugs; COX-2 = cyclooxygenase 2; TEP = Technical Expert Panel.

with either topical or oral NSAIDs, topical capsaicin, or tramadol (Table 2). The TEP conditionally recommends that such patients not be treated with opioid analgesics or intraarticular therapies.

For patients with involvement of the trapeziometacarpal joint who request an intraarticular injection, the TEP conditionally recommends not using either intraarticular corticosteroids or hyaluronates and, furthermore, provided no recommendation on the choice between corticosteroids and hyaluronates, if a provider decides to give an injection. For patients with erosive and/or inflammatory interphalangeal OA, the TEP conditionally recommends not using either oral methotrexate or sulfasalazine and voted not to provide a recommendation either for or against the use of hydroxychloroquine. The recommendations not to use modalities were based largely on the absence of evidence from RCTs to support the benefits of use of these modalities and the potential for harm from these agents and/or procedures.

Knee OA. *Base case.* An adult with symptomatic knee OA without cardiovascular comorbidities, current or past upper GI problems, or chronic kidney disease presents to her primary care provider for treatment. She experiences pain in and/or around her knee(s) and has not had an adequate response to either intermittent dosing of OTC acetaminophen, OTC NSAIDs, or OTC nutritional supplements (e.g., chondroitin sulfate, glucosamine).

Nonpharmacologic modalities. The TEP strongly recommends that all patients with symptomatic knee OA be enrolled in an exercise program commensurate with their ability to perform these activities (25,26) (Table 3). The TEP expressed no preference for aquatic exercises as opposed to land-based exercises based on benefits or safety; the decision should be individualized and based on patient preferences and ability to perform exercises. For example, a patient who is aerobically deconditioned should initially participate in an aquatic exercise program in order to improve their aerobic capacity. Once this is accomplished, they can progress to a land-based program and choose, in conjunction with their health care provider, an aerobic conditioning or strengthening program or both. The TEP also strongly recommends that all patients with symptomatic knee OA who are overweight be counseled regarding weight loss (27).

The TEP conditionally recommends that patients with knee OA should 1) participate in self-management programs that may include psychosocial interventions, 2) use thermal agents and manual therapy in combination with exercise supervised by a physical therapist, 3) use medially directed patellar taping, 4) participate in tai chi programs, and 5) use walking aids, if necessary. Patients with lateral compartment OA are conditionally recommended to wear medially wedged insoles, while those with medial compartment OA are conditionally recommended to wear laterally wedged subtalar strapped insoles.

Pharmacologic modalities. For the base case failing to obtain adequate pain relief with intermittent dosing of OTC acetaminophen, OTC NSAIDs, and/or OTC nutritional supplements (e.g., chondroitin sulfate, glucosamine), the TEP conditionally recommends that health

Table 3. Nonpharmacologic recommendations for the management of knee OA

We strongly recommend that patients with knee OA should do the following:
Participate in cardiovascular (aerobic) and/or resistance land-based exercise
Participate in aquatic exercise
Lose weight (for persons who are overweight)
We conditionally recommend that patients with knee OA should do the following:
Participate in self-management programs
Receive manual therapy in combination with supervised exercise
Receive psychosocial interventions
Use medially directed patellar taping
Wear medially wedged insoles if they have lateral compartment OA
Wear laterally wedged subtalar strapped insoles if they have medial compartment OA
Be instructed in the use of thermal agents
Receive walking aids, as needed
Participate in tai chi programs
Be treated with traditional Chinese acupuncture*
Be instructed in the use of transcutaneous electrical stimulation*
We have no recommendations regarding the following:
Participation in balance exercises, either alone or in combination with strengthening exercises
Wearing laterally wedged insoles
Receiving manual therapy alone
Wearing knee braces
Using laterally directed patellar taping

* These modalities are conditionally recommended only when the patient with knee osteoarthritis (OA) has chronic moderate to severe pain and is a candidate for total knee arthroplasty but either is unwilling to undergo the procedure, has comorbid medical conditions, or is taking concomitant medications that lead to a relative or absolute contraindication to surgery or a decision by the surgeon not to recommend the procedure.

Table 4. Pharmacologic recommendations for the initial management of knee OA*

We conditionally recommend that patients with knee OA should use one of the following:
Acetaminophen
Oral NSAIDs
Topical NSAIDs
Tramadol
Intraarticular corticosteroid injections
We conditionally recommend that patients with knee OA should not use the following:
Chondroitin sulfate
Glucosamine
Topical capsaicin
We have no recommendations regarding the use of intraarticular hyaluronates, duloxetine, and opioid analgesics

* No strong recommendations were made for the initial pharmacologic management of knee osteoarthritis (OA). For patients who have an inadequate response to initial pharmacologic management, please see the Results for alternative strategies. NSAIDs = nonsteroidal antiinflammatory drugs.

care providers can use acetaminophen, oral or topical NSAIDs, tramadol, or intraarticular corticosteroid injections (Table 4). The TEP conditionally recommends that health care providers do not use nutritional supplements (e.g., chondroitin sulfate, glucosamine) or topical capsaicin. If the health care provider chooses to initiate acetaminophen in the full dosage up to 4,000 mg/day, the patient should be counseled to avoid all other products that contain acetaminophen, including OTC cold remedies as well as combination products with opioid analgesics.

If the patient does not have a satisfactory clinical response to full-dose acetaminophen, then the TEP strongly recommends the use of oral or topical NSAIDs or intraarticular corticosteroid injections (18,19). Health care providers should not use oral NSAIDs in patients with contraindications to these agents and should be aware of the warnings and precautions associated with the use of these agents. Furthermore, for persons age ≥75 years, the TEP strongly recommends the use of topical rather than oral NSAIDs (28). In this scenario, the TEP conditionally recommends the use of tramadol, duloxetine, or intraarticular hyaluronan injections. If the patient has a history of a symptomatic or complicated upper GI ulcer but has not had an upper GI bleed in the past year and the practitioner chooses to use an oral NSAID, the TEP strongly recommends using either a cyclooxygenase 2 (COX-2) selective inhibitor or a nonselective NSAID in combination with a proton-pump inhibitor; there was no preference expressed between these choices (29). In the clinical scenario where the above patient has had an upper GI bleed within the past year and the practitioner still chooses to use an oral NSAID, the TEP strongly recommends using a COX-2 selective inhibitor in combination with a proton-pump inhibitor. Subsequent to the initial meeting of the TEP, Latimer and colleagues reported that the addition of a proton-pump inhibitor to either a nonselective or COX-2 selective NSAID is cost effective given the evolving evidence base for efficacy and reductions in price (30). Therefore, whenever an NSAID is used for the chronic management of patients with knee or hip OA, the practitioner should consider adding a proton-pump inhibitor to reduce the risk of development of symptomatic or complicated upper GI events.

In the clinical scenario where the patient with OA is taking low-dose aspirin (≤325 mg per day) for cardioprotection and the practitioner chooses to use an oral NSAID, the TEP strongly recommends using a nonselective NSAID other than ibuprofen in combination with a proton-pump inhibitor. This recommendation is based, in part, on the FDA warning that the concomitant use of ibuprofen and low-dose aspirin may render aspirin less effective when used for cardioprotection and stroke prevention because of a recognized pharmacodynamic interaction (31,32). Studies have not demonstrated this same type of pharmacodynamic interaction with diclofenac or celecoxib (33,34); nonetheless, the TEP strongly recommends that a COX-2 selective inhibitor should not be used in the above situation. No specific recommendation was made regarding other individual NSAIDs.

Based on good clinical practice, oral NSAIDs should not be used in patients with chronic kidney disease stage IV or V (estimated glomerular filtration rate below 30 cc/minute); the decision to use an oral NSAID in patients with chronic kidney disease stage III (estimated glomerular filtration rate between 30 and 59 cc/minute) should be made by the practitioner on an individual basis after consideration of the benefits and risks.

Finally, for patients with symptomatic knee OA who have not had an adequate response to both nonpharmacologic and pharmacologic modalities and are either unwilling to undergo or are not candidates for total joint arthroplasty, the TEP strongly recommends the use of opioid analgesics and conditionally recommends the use of duloxetine. The authors suggest that practitioners follow the recommendations of the American Pain Society/American Academy of Pain Medicine for the use of opioid analgesics in the management of their chronic noncancer pain (35). These recommendations provide guidance on 1) patient selection and risk stratification, 2) informed consent and opioid management plans, 3) initiation and titration of chronic opioid therapy, 4) monitoring of patients on chronic opioid therapy, including dose escalations, high-dose opioid therapy, opioid rotation, and indications for discontinuation of therapy, 5) prevention and management of opioid-related adverse effects, and 6) management of breakthrough pain.

Treatment with traditional Chinese acupuncture or instruction in the use of transcutaneous electrical stimulation are conditionally recommended only when the patient with knee OA has chronic moderate to severe pain and is a candidate for total knee arthroplasty but either is unwilling to undergo the procedure, has comorbid medical conditions, or is taking concomitant medications that lead to a relative or absolute contraindication to surgery or a decision by the surgeon not to recommend the procedure (Table 3).

Hip OA. *Base case.* An adult with symptomatic hip OA without cardiovascular comorbidities, current or past up-

per GI problems, or chronic kidney disease presents to her primary care provider for treatment. As few trials have been performed in patients with symptomatic hip OA, the TEP considered that patients with hip OA should be treated in a similar fashion to those with knee OA except for selected differences.

Nonpharmacologic modalities. The TEP strongly recommends that all patients with symptomatic hip OA be enrolled in an exercise program commensurate with their ability to perform these activities (Table 5). The TEP expressed no preference for aquatic exercises as opposed to land-based exercises based on benefits or safety; the decision should be individualized and based on patient preferences and the ability to perform exercises. The TEP strongly recommends that all patients with symptomatic hip OA who are overweight be counseled regarding weight loss.

The TEP conditionally recommends that patients with hip OA should 1) participate in self-management programs that may include psychosocial interventions, 2) use thermal agents and manual therapy in combination with exercise supervised by a physical therapist, and 3) use walking aids, if necessary. Interventions for which data are available only for knee OA and not hip OA were not considered for patients with only hip OA (e.g., insoles, patellar taping, acupuncture, transcutaneous electrical stimulation, tai chi).

Pharmacologic modalities. The approach to pharmacologic therapy for the patient with hip OA is similar to that for the patient with knee OA except that no recommendations were made for intraarticular hyaluronates, duloxetine, or topical NSAIDs because of the lack of data from RCTs on either benefit or safety at the time of the TEP meeting in December 2008 (Table 6). Again, opioid analgesics are strongly recommended only for patients with symptomatic hip OA who have not had an adequate response to both nonpharmacologic and pharmacologic modalities and are either unwilling to undergo or are not candidates for total joint arthroplasty.

Table 5. Nonpharmacologic recommendations for the management of hip osteoarthritis (OA)

We strongly recommend that patients with hip OA should do the following:
Participate in cardiovascular and/or resistance land-based exercise
Participate in aquatic exercise
Lose weight (for persons who are overweight)
We conditionally recommend that patients with hip OA should do the following:
Participate in self-management programs
Receive manual therapy in combination with supervised exercise
Receive psychosocial interventions
Be instructed in the use of thermal agents
Receive walking aids, as needed
We have no recommendations regarding the following:
Participation in balance exercises, either alone or in combination with strengthening exercises
Participation in tai chi
Receiving manual therapy alone

Table 6. Pharmacologic recommendations for the initial management of hip OA*

We conditionally recommend that patients with hip OA should use one of the following:
Acetaminophen
Oral NSAIDs
Tramadol
Intraarticular corticosteroid injections
We conditionally recommend that patients with hip OA should not use the following:
Chondroitin sulfate
Glucosamine
We have no recommendation regarding the use of the following:
Topical NSAIDs
Intraarticular hyaluronate injections
Duloxetine
Opioid analgesics

* No strong recommendations were made for the initial pharmacologic management of hip osteoarthritis (OA). For patients who have an inadequate response to initial pharmacologic management, please see the Results for alternative strategies. NSAIDs = nonsteroidal antiinflammatory drugs.

DISCUSSION

These ACR 2012 recommendations for the management of patients with hand, hip, and knee OA are based on the best available evidence of benefit and safety/tolerability of both nonpharmacologic and pharmacologic interventions as well as the consensus judgment of clinical experts from a wide range of disciplines balancing the benefits and harms of these treatments and incorporating their preferences and values. We used the GRADE approach, which provides a comprehensive, explicit, and transparent methodology for developing recommendations for the management of patients (10–14,23,36). We included modalities that had been reviewed by other groups of experts in their recommendations published during the last decade (4–7,37) as well as modalities that have been investigated since the publication of these recommendations. The TEP was provided with a series of documents including not only the results of literature reviews, which provided the best available evidence to support the benefit and safety of pharmacologic and nonpharmacologic modalities, but also published recommendations from other professional societies (see above) prior to their voting. In addition, the TEP received documentation and formal instruction on implementation of the methodology. Therefore, these recommendations represent evidence- and expert consensus–based recommendations that should serve as a guide to health care providers in their approach to the management of patients with symptomatic OA. It is hoped that they may also be useful for the development and/or modification of quality measures for OA (38,39). As new evidence continues to be developed, it is likely that these recommendations will need to be updated and/or revised; such revisions will be posted, as appropriate, on the ACR web site (http://www.rheumatology.org/).

The authors acknowledge that, while most of the recommendations will not be controversial, some may be met

with disagreement by health care practitioners. One example is that of conditionally recommending against the use of glucosamine and chondroitin sulfate for patients with knee OA. The TEP relied initially on the results of the Glucosamine/Chondroitin Arthritis Intervention Trial (40) and meta-analyses that demonstrated significant heterogeneity in effect size (41–43) coupled with the lack of availability of prescription-quality preparations evaluated and approved for the indication of OA by the FDA. This original decision was reaffirmed after reviewing the results of a more recent network meta-analysis that also failed to demonstrate clinically important efficacy for these agents (44).

There have been many developments in the scientific and clinical understanding of OA in the past decade since the publication of the 2000 revised ACR recommendations (45,46). One of these developments is the publication of recommendations for the management of OA by numerous professional societies. These 2012 ACR OA guidelines improve upon these other recommendations in several ways. First, they are based on evidence available through the end of 2010. Second, they include recommendations for the management of hand OA as well as knee and hip OA. Third, they were developed using a rigorous transparent guideline development methodology that has been increasingly used by guideline developers in recent years. Finally, participants included the broadest group of experts to date on an OA guideline development project, representing several disciplines of health care providers with an interest in OA management.

When comparing these ACR guidelines to recent EULAR and OARSI guidelines, all rely on consensus recommendations based on the evidence. The EULAR recommendations are based on commissioned systematic reviews of the literature on both nonpharmacologic and pharmacologic modalities for OA of the hand, hip, and knee. OARSI commissioned a systematic review of the literature that updated those conducted for EULAR for OA of the hip and knee. Herein, literature reviews were conducted to identify the best available systematic review(s) and meta-analysis(es) for each of the modalities and, if these were not available, then the best available RCTs were selected.

All of the groups used a form of expert panel to provide the consensus recommendations. For the recommendations on hip and knee OA, the EULAR panel consisted of only rheumatologists and orthopedic surgeons; for the hand OA recommendations, EULAR added a physiatrist and 2 allied health professionals. The OARSI panel included 2 primary care physicians in addition to rheumatologists and an orthopedic surgeon. The ACR is the only professional society to include primary care physicians, physiatrists, and geriatricians along with rheumatologists (both academic and private practice), an orthopedic surgeon, and both physical and occupational therapists. Furthermore, the TEP had both sex and ethnic representations from constituencies within the ACR as well as members from both the US and Canada.

Both EULAR and OARSI used modifications of the Delphi technique to generate lists of propositions. This process required members of the Steering and Guideline Development Committees to amalgamate and rewrite or reword individual propositions submitted by members of the individual expert committees in order to reach consensus. The current ACR recommendations were developed using the GRADE process, a comprehensive, explicit, and transparent methodology that does not include the use of propositions; rather, the TEP used the best available evidence for the benefits and safety of each modality to produce specific recommendations, either strong, conditional, or none, for the use of each modality relative to a specific clinical scenario. These ACR recommendations acknowledge the values and preferences of the panel members for the desirable and undesirable outcomes of each modality.

It is hoped that with appropriate dissemination, these revised ACR guidelines will be utilized by health care providers in the management of their patients with OA.

Addendum. Therapies that were approved after the literature reviews are not included in these recommendations.

ACKNOWLEDGMENTS

The authors would like to acknowledge Elizabeth Tanjong Ghogomum, Lara Maxwell, Tamara Rader, and Erin Ueffing from the University of Ottawa for their assistance with the Ottawa team in preparing documentation for the panel members, and Amy Miller from the ACR for her support during this process.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Hochberg had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

APPENDIX A: MEMBERS OF THE TECHNICAL EXPERT PANEL

Members of the Technical Expert Panel are as follows: Roy D. Altman, MD (Chair): David Geffen School of Medicine, University of California, Los Angeles; Catherine L. Backman, PhD, OT: University of British Columbia, Vancouver, British Columbia, Canada; Lee I. Blecher, MD: Virginia Commonwealth University School of Medicine, Richmond, and Private Practice, Fairfax, Virginia; G. Kelley Fitzgerald, PhD, PT, C. Kent Kwoh, MD: University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania; F. Michael Gloth, MD: The Johns Hopkins University School of Medicine, Baltimore, Maryland; Victor Goldberg, MD: Case Western Reserve University School of Medicine, Cleveland, Ohio; William McCarberg, MD: Kaiser Permanente, San Diego, California; Stephanie McGann, MD: University of Maryland School of Medicine, Baltimore (current address: Private Practice, Laurel, Maryland); Carol A. Oatis, PhD, PT: Arcadia University, Glenside, Pennsylvania; Robert Pallay, MD: Private Practice, Savannah, Georgia; Thomas J. Schnitzer, MD, PhD: Rehabilitation Institute of Chicago and Northwestern University, Chicago, Illinois; Radames Sierra-Zorita, MD: Private Practice, San Juan, Puerto Rico; Todd Stitik, MD: University of Medicine and Dentistry of New Jersey–New Jersey Medical School, Newark.

ACR OA Guidelines
Non-pharmacological - Knee and Hip
September 2009

Table of Contents

1. EXERCISE 4

1.1 Balance exercises 4
1.1.1 Home-based balance exercises versus home-based strengthening exercises for knee OA 4
1.1.2 Balance exercises in addition to strengthening exercises versus strengthening exercises alone for knee OA 8

1.2 Land-based exercise 12
1.2.1 Cardiovascular land-based exercise versus usual care for knee OA 12
1.2.2 Resistance land-based exercise versus usual care for knee OA 16

1.3 Aquatic exercises 19
1.3.1 Aquatic exercise versus no exercise for OA of hip or knee 19
1.3.2 Aquatic exercise versus land-based exercise of knee OA 23

1.4 Tai chi 27

1.5 General hip exercise 31

2. INSOLES 34

2.1 Laterally wedged insoles versus neutrally wedged insoles for knee OA 34

2.2 Medial wedged insoles versus neutrally wedged insoles for knee OA 37

2.3. Subtalar strapped insoles versus inserted laterally wedged insoles for knee OA 40

3. SELF-MANAGEMENT 45

4. MANUAL THERAPY 49

4.1 Manual therapy program versus exercise therapy program for hip OA 49

4.2 Manual therapy in combination with supervised exercise and home exercise program versus home exercise program alone for knee OA 56

5. PSYCHOSOCIAL INTERVENTIONS 60

6. WEIGHT LOSS 64

7. BRACES 67

7.1 Braces and medical (conservative) treatment versus medical (conservative) treatment in knee OA 67

7.2 Braces with medical (conservative) treatment versus medical (conservative) treatment alone in knee OA 71

7.3 Braces and medical treatment versus neoprene sleeve with medical treatment in knee OA..... 74

8. TAPING 78

8.1 Medially-directed patellar taping versus no taping in knee OA 78

8.2 Medially-directed patellar taping versus sham taping in knee OA..... 82

8.3 Laterally-directed patellar taping versus medially-directed patellar taping in knee OA..... 87

8.4 Laterally-directed patellar taping versus neutral sham taping in knee OA..... 91

1. EXERCISE

1.1 Balance exercises

1.1.1 Home-based balance exercises versus home-based strengthening exercises for knee OA

Are balance exercises effective in reducing pain and improving function in patients with symptomatic knee OA compared to strengthening exercises?

Step 1: Search Results

There were no SRs which reported the efficacy of balance exercises specifically in patients with OA (Orr, 2008, assessed the efficacy of progressive resistive training which is a different treatment and Howe, 2007 did not report any study with OA patients). There was one RCT which assessed the efficacy of balance exercises versus strengthening exercises in OA patients: Chaipinyo, 2009.

Intervention description: Participants in the balance group performed 30 repetitions of stepping forward and backward then sideways for each leg, 5 days a week for 4 weeks. They also performed 30 repetitions of a bilateral mini squat within pain free range (i.e., 15-30 degrees of knee flexion) in order to strengthen the quadriceps muscle in standing. The sequence of the exercises was as follows: stepping forward and backward with left leg 30 times, bilateral mini squat 10 times, stepping forward and backward with right leg 30 times, bilateral mini squat 10 times, stepping sideward to the left 30 times, bilateral mini squat 10 times, stepping sideward to the right 30 times. Exercises were performed at home.

Step 2: GRADE Summary of findings

*This study has a small sample size (n=42), which could undermine its validity.
*Participants in the strength group performed 30 repetitions of isometric knee extension in sitting for each leg, 5 days a week.

Home-based balance training compared to home-based strength training for knee OA

Patient or population: patients with knee OA
Intervention: home-based balance training
Comparison: home-based strength training

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **strength training**	Corresponding risk **Balance training**					
Benefits							
Pain Knee injury and Osteoarthritis Outcome Score (KOOS). Scale from: 0 to 100. Follow-up: 4 weeks	30%	22% (8% to 44%)[1]	-8%	0.73	42 (1 study)	⊕⊕OO low[2,3,4]	Not statistically significant *Balance training shows less improvement in pain than strength training.
function in daily living Knee injury and Osteoarthritis Outcome Score (KOOS). Scale from: 0 to 100. Follow-up: 4 weeks	28%	15% (5% to 34%)[1]	-13%	0.54	42 (1 study)	⊕⊕OO low[2,3,4]	Not statistically significant *Balance training shows less improvement in function than strength training.
Harms							
Adherence (average number of days of exercise performed by participants) Maximum number of days:28. Follow-up: 4 weeks	Mean (SD) 19 (3)	Mean (SD) 21 (6)	MD 2 (-0.77 to 4.77)	-	42 (1 study)	⊕⊕OO low[2,3,4]	Not statistically significant *Balance training shows better adherence than strength training.
Withdrawals (patients who withdrew from the study after randomization) Follow-up: 4 weeks	25%	2% (0% to 32%)[5]	-23%	0.08 (0.00 to 1.29)	48 (1 study)	⊕⊕OO low[2,3,4]	Not statistically significant *Balance training shows less withdrawals than strength training.
Safety				Not reported			

[1] The authors report the mean difference over time between groups but it does not coincide with our results using Rev Man 5 because the authors did not report the level of accuracy needed (no decimals reported). We calculated the SMD using Rev Man 5.
[2] The physiotherapists prescribing the exercises were not blinded to group allocation. We did not downgrade the quality assessment score for this. However, the number of patients in this trial is small (n=42), which could undermine its validity.
[3] Participants were volunteers from the community 50 years and older. We did not downgrade the quality assessment score for this.
[4] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[5] Withdrawals were due to other illnesses, personal reasons or impossibility to reach patients.

Visual Summary of findings figure:
Home-based balance training compared to home-based strength training for knee OA

Chance: Improving pain after 4 weeks	
NNT: n/a	**Not statistically significant**
😐 70 people out of 100 don't improve with either type of training.	
🙂 22 people out of 100 improve with either type of training.	
😐 **8 FEWER people** out of 100 improve with balance training at home.	
Chance: Improving function after 4 weeks	
NNT: n/a	**Not statistically significant**
😐 72 people out of 100 don't improve with either type of training.	
🙂 15 people out of 100 improve with either type of training.	
😐 **13 FEWER people** out of 100 improve with balance training at home.	
Chance: Adherence after 4 weeks	
NNH: n/a	**Not statistically significant**
😐 On average, people performed the exercises for 19 days with either type of training	
☹ On average, people did not perform the exercises for 7 days (out of maximum possible of 28 days) with either type of training	
☹ On average, people performed exercises for **2 less** days with strengthening than balance training at home.	
Chance: Withrawals from the trials after 4 weeks	
NNH: n/a	**Not statistically significant**
😐 75 people out of 100 did not drop out of either type of training.	
☹ 2 people out of 100 dropped out of either type of training..	
🙂 **23 fewer people** out of 100 dropped out of balance training at home.	

Step 3: GRADE Evidence profile
See Table 1 a: Home-based balance exercises versus home-based strengthening exercises

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	We recommend patients with symptomatic OA of the knee be encouraged to participate in low-impact aerobic fitness exercises. Range of motion/flexibility exercises are an option for patients with symptomatic OA of the knee. We suggest quadriceps strengthening for patients with symptomatic OA of the knee.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, *insoles*, knee bracing) and weight reduction.
OARSI	Patients with hip and knee OA should be encouraged to undertake, and continue to undertake, regular aerobic, muscle strengthening and range of motion exercises.

Step 5: GRADE Recommendation

References

1.1.2 Balance exercises in addition to strengthening exercises versus strengthening exercises alone for knee OA

Are balance exercises in addition to strengthening exercises effective in reducing pain and improving function in patients with symptomatic OA compared to strengthening exercises alone?

Step 1: Search Results

There were no SRs which reported the efficacy of balance exercises specifically in patients with OA (Orr, 2008 assessed the efficacy of progressive resistive training which is a different treatment and Howe, 2007 did not report any study with OA patients). There was one RCT which assessed the efficacy of balance exercises in addition to strengthening exercises vs. strengthening exercises alone (Diracoglu, 2005).

Intervention description: The first group (kinesthesia group) received kinesthesia, balance, and strengthening exercises and the second group (strengthening group) received only strengthening exercises. Patients in both groups were informed about knee OA and protective recommendations for the knee were made. The exercises were done 3 days a week in groups of 5 people in a clinical setting under the supervision of a physiotherapist. The total duration of the exercises was determined as 8 weeks. Isometric exercises were applied with 6-second contractions with 8 repetitions and a rest period of 2 seconds. Isotonic exercises were started from the third week and the maximum weight that can be lifted 10 times (10-repetition maximum = 10 RM) was determined. The exercises were applied as 10 repetitions with half of this weight, 10 repetitions with three fourths of this weight, and 10 repetitions with the whole 10 RM.10 RM was determined again every week.

Step 2: GRADE Summary of findings

kinesthesia and balance exercises in addition to strengthening exercises compared to strengthening exercises for knee OA

Patient or population: patients with knee OA
Intervention: kinesthesia and balance exercises in addition to strengthening exercises
Comparison: strengthening exercises

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk	Corresponding risk					
	strengthening exercises	kinesthesia and balance exercises in addition to strengthening exercises					
Benefits							

Physical function WOMAC. Scale from: 0 to 10. Follow-up: 8 weeks	31%	48% (29% to 68%)[1]	17%	1.55	60 (1 study)	⊕⊕OO low[2,3,4]	Not statistically significant
Pain	No evidence available[5]						
Harms							
Adverse effects number of patients with event Follow-up: 8 weeks	0%	0%	0%	1	60 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Adherence mean number of missed visits Maximum number of visits:24 Follow-up: 8 weeks	Mean 6	Mean 4	MD -2	-	48 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Withdrawals number of patients who withdrew after randomization Follow-up: 8 weeks	9%	9% (2% to 42%)[6]	0%	1 (0.22 to 4.6)	66 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant

[1] The authors reported the end of study results in both groups, which showed a statistically significant difference. However, their results did not coincide with our results from Rev Man 5 because the authors did not report the level of accuracy needed.
[2] The randomization method used is the "one-to-one" method which allocates one patient to the study group and the other patient to the control group one by one according to their order of application to the outpatient clinic. This method could lead to biases. Furthermore, blinding was not reported and intention to treat analyses were not performed.
[3] All patients included in the study were women 35 to 65 years old. We did not downgrade the quality of the study because of this.
[4] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[5] Pain was not measured in the RCT. However, the use of paracetamol was reported, which could represent a proxy measure for pain to some extent. The authors report that 5 patients used paracetamol during the study in a dosage of less than 500 mg daily. The 2 groups were not significantly different from each other regarding paracetamol use ($P > 0.05$).
[6] Patients withdrew because of the difficulty to come to the clinic for exercises.

Visual Summary of findings figure:
Kinesthesia and balance exercises in addition to strengthening exercises compared to strengthening exercises for knee OA

<table>

1.2 Land-based exercise

1.2.1 Cardiovascular land-based exercise versus usual care for knee OA

Is cardiovascular land exercise effective in reducing pain and improving function in patients with symptomatic knee osteoarthritis (OA) compared to usual care?

Step 1: Search Results

Three systematic reviews (SR) were found. Pisters (2007), was excluded from this comparison because it did not provide a description of the exercises used (combination of land, water, balance) and it did not report adherence. The second, Hart (2008), was excluded because it did not focus on osteoarthritis patients. Therefore, Fransen (2008) was chosen as the best available evidence. One overview of SRs on therapeutic exercise was found (Taylor, 2007) and its overall conclusions followed those of the chosen SR. Four randomized controlled trials published after the chosen SR were also found (Chua, 2008; Lund, 2008; Dincer, 2008; Olejarova, 2008). Their results were largely similar to those of the chosen SR. Evidence for withdrawals were extracted from the best RCT from Fransen, 2008: Ettinger, 1997.

Interventions description: non-perioperative walking program

Step 2: GRADE Summary of findings

	cardiovascular land exercise compared to no exercise for osteoarthritis of the knee						
	Patient or population: patients with osteoarthritis of the knee **Settings:** **Intervention:** cardiovascular land exercise **Comparison:** no exercise						
Outcomes	**Illustrative comparative risks* (95% CI)** Assumed risk **no exercise**	Corresponding risk **cardiovascular land exercise**	**Absolute difference**	**Relative effect (95% CI)**	**No of Participants (studies)**	**Quality of the evidence (GRADE)**	**NNT**
Benefits							
pain pooled studies with different scales including WOMAC and VAS amongst others	24%	41% of those cardiovascular exercise group experienced a decrease in pain (31% to 55%)	17%	1.71	351 (4[3])	⊕⊕⊕⊕ **high**[1]	5 (3 to 12)

function pooled studies with different scales including WOMAC and VAS amongst others	22%	34% of those cardiovascular exercise group experienced a decrease in pain (26% to 43%)	12%	1.55	317 (3[4])	⊕⊕⊕⊕ **high**[1]	7 (4 to 20)
Harms							
withdrawals number of (follow-up: mean 18 months)	**15%**	**19%** (11% to 31%)	**4%**	**RR 1.27** (0.76 to 2.12)	293 (1[5])	⊕⊕⊕O **moderate**	Not statistically significant
Safety (falls while walking)	1.4% of intervention group fell during walking (2/144)			**RR 5.17** (0.25 to 106.82)	293 (1[5])	⊕⊕⊕O **moderate**	Not statistically significant
Adherence	**95%**	**68%** (60% to 76%)	**27%**	**RR 0.71** (0.63 to 0.80)	293 (1[5])	⊕⊕⊕⊕ **high**	5 (4 to 7)

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio;

GRADE Working Group grades of evidence
High quality: Further research is very unlikely to change our confidence in the estimate of effect.
Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

[1] Evidence mostly included participants with early or mild symptomatic disease.
[3] Minor 1989, Ettinger 1997, Bautch 1997, Talbot 2003
[4] Minor 1989, Ettinger 1997, Bautch 1997
[5] Is imprecise; includes no effect and significant benefit (0.76, 2.12)
[6] Ettinger 1997

Visual Summary of Findings Table
Cardiovascular land exercise compared to no exercise for osteoarthritis of the knee

Chance: Improving pain

NNT: 5

59 people out of 100 don't improve whether or not they exercise.

24 people out of 100 improve whether or not they exercise.

17 more people out of 100 improve with cardiovascular land-based exercise.

Chance: Improving function

NNT: 7		
😐	66 people out of 100 don't improve whether or not they exercise.	
🙂	22 people out of 100 improve whether or not they exercise.	
🙂	**12 more people** out of 100 improve with land-based cardiovascular exercise	
Chance: Withdrawls after 18 months		
NNH: n/a		**Not statistically significant**
😐	85 people out of 100 did not leave the study whether they exercised or not.	
☹	9 people out of 100 left the study whether they exercised or not.	
☹	**4 more** people out of 100 left the study when they did land-based exercise.	
Chance: Safety		
1 person out 100 fell while walking		
Chance: Adherence*		
NNH: 5		
😐	68 people out of 100 adhered to either exercise or their normal activities	
☹	5 people out of 100 did not adhere to either exercise or their normal activities.	
☹	**27 more** people out of 100 did not adhere to the exercise.	

*does not add up to 100 due to rounding.

Step 3: GRADE Evidence profile

See Table 1 c: Cardiovascular land-based exercise versus usual care

Step 4: Other recommendations

Group	Recommendation
EULAR	Non-pharmacological treatment of knee OA should include education, *exercise*, appliances (sticks, insoles, knee bracing) and weight reduction.
OARSI	Patients with hip and knee OA should be encouraged to undertake, and continue to undertake, regular aerobic, muscle strengthening and range of motion exercises. For patients with systematic hip OA, exercises in the water can be effective.
AAOS (knee only)	We recommend patients with symptomatic OA of the knee be encouraged to participate in low-impact aerobic fitness exercises. Range of motion/flexibility exercises are an option for patients with symptomatic OA of the knee. We suggest quadriceps strengthening for patients with symptomatic OA of the knee.

Step 5: GRADE Recommendation

1.2.2 Resistance land-based exercise versus usual care for knee OA

Is resistance land exercise effective in reducing pain and improving function in patients with symptomatic knee OA compared to usual care?

Step 1: Search Results

Three systematic reviews (SR) were found. One, Pisters (2007), was excluded from this comparison because it did not provide a description of the exercises used (combination of land, water, balance) and it did not report adherence. The second, Hart (2008), was excluded because it did not focus on osteoarthritis patients. Therefore, Fransen (2008) was chosen as best available evidence. One overview of SR on therapeutic exercise was found (Taylor, 2007) and its overall conclusions followed those of the chosen SR. Four randomized controlled trials published after the chosen SR were also found (Chua, 2008; Lund, 2008; Dincer, 2008; Olejarova, 2008). Their results were largely similar to those of the chosen evidence. Safety, adherence, and withdrawals were not included in the best RCT included in Fransen, 2008 (Huang, 2005).

Intervention description: non-perioperative lower limb muscle strengthening

Step 2: GRADE Summary of findings

resistance land exercise compared to no exercise for knee OA

Patient or population: patients with osteoarthritis of the knee
Settings:
Intervention: resistance land exercise
Comparison: no exercise

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk	Corresponding risk					
	no exercise	**resistance land exercise**					
Benefits							
Pain pooled studies with different scales including WOMAC and VAS amongst others	32%	53% of those in strengthening exercise group experienced a decrease in pain (43% to 63%)	21%	1.66	1383 (9[3])	⊕⊕⊕O **moderate**[1,2]	4 (3 to 8)
Function pooled studies with different scales including	10%	25% of those in strengthening exercise group experienced a decrease in pain	15%	2.5	1383 (9[3])	⊕⊕⊕O **moderate**[1,2]	6 (4 to 22)

WOMAC and VAS amongst others		(35% to 69%)					
Harms							
Safety	14% patients in exercise group stopped due to intolerable pain during exercise.						
Adherence	Not reported						
Withdrawals	**9%**	**14%** (4 to 56%)	**5%**	**RR 1.67** (0.43 to 6.45)	70 (1[4])	⊕⊕⊕⊕ **high**	Not statistically significant

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval;

GRADE Working Group grades of evidence
High quality: Further research is very unlikely to change our confidence in the estimate of effect.
Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

[1] Evidence mostly included participants with early or mild symptomatic disease.
[2] Large confidence interval ranging from small to large effect
[3] Schilke 2006, Ettinger 1997, Baker 2001, Thomas 2002, Gur 2002, Huang 2003, Huang 2005, Thorstensson 2005, Mikesky 2006

Visual Summary of Findings Table
Resistance land exercise compared to no exercise for osteoarthritis of the knee

Chance: Improving pain

NNT: 4

47 people out of 100 don't improve whether or not they exercise.

32 people out of 100 improve whether or not they exercise.

21 more people out of 100 improve with exercise.

Chance: Improving function

NNT: 6

75 people out of 100 don't improve whether or not they exercise.

☺	10 people out of 100 improve whether or not they exercise.	
☺	**15 more people** out of 100 improve with exercise	
Chance: Withdrawals		
NNH: n/a		**Not statistically significant**
😐	86 people out of 100 did not leave the study whether they exercised or not.	
☹	9 people out of 100 left the study whether they exercised or not.	
☹	**5 more** people out of 100 left the study in the lower limb exercise group.	
Chance: Safety		
14% patients in exercise group stopped due to intolerable pain during exercise.		
Chance: Adherence		
The number of people who adhered to resistance exercise was not reported.		

Step 3: GRADE Evidence profile
See Table 1 d: Resistance land-based exercise versus usual care

Step 4: Other recommendations

Group	Recommendation
AAOS (knee only)	We recommend patients with symptomatic OA of the knee be encouraged to participate in low-impact aerobic fitness exercises. Range of motion/flexibility exercises are an option for patients with symptomatic OA of the knee. We suggest quadriceps strengthening for patients with symptomatic OA of the knee.
EULAR	Non-pharmacological treatment of knee OA should include education, *exercise*, appliances (sticks, insoles, knee bracing) and weight reduction.
OARSI	Patients with hip and knee OA should be encouraged to undertake, and continue to undertake, regular aerobic, muscle strengthening and range of motion exercises. For patients with systematic hip OA, exercises in the water can be effective.

Step 5: GRADE Recommendation

1.3 Aquatic exercises

1.3.1 Aquatic exercise versus no exercise for OA of hip or knee

Is aquatic exercise effective in reducing pain and improving function in patients with symptomatic knee and hip OA compared to usual care?
Interventions description: All types of exercises developed in the therapeutic/heated indoor pool (range of motion, dynamics, aerobics, etc.).

Step 1: Search Results
Only one meta-analysis was found that assessed aquatic exercise for knee osteoarthritis (Bartels, 2007). Two more recent randomized controlled trials were also found (Lund, 2008; Gill, 2009). Although Lund (2008) found no improvement following aquatic exercise, Gill (2009) found similar results to those reported below whereby pain was decreased.

**** NOTE:** This evidence is the same as that found in the hip exercise summary of findings because data from both joints were pooled******

Step 2: GRADE Summary of findings

	aquatic exercise compared to no exercise for osteoarthritis of hip or knee						
	Patient or population: patients with osteoarthritis of hip or knee **Settings:** **Intervention:** aquatic exercise **Comparison:** no exercise						
Outcomes	**Illustrative comparative risks* (95% CI)** Assumed risk **no exercise**	Corresponding risk **aquatic exercise**	**Relative effect (95% CI)**	**Absolute difference**	**No of Participants (studies)**	**Quality of the evidence (GRADE)**	**NNT**
Benefits							

Pain after intervention Pooled different scales[1]	34%	41% of those in aquatic exercise group experienced a decrease in pain (35% to 48%)	1.2	7%	638 (4[3])	⊕⊕⊕⊕ **high**[2]	11 (6 to 52)
Pain follow up WOMAC pain . Scale from: 0 to 20. (follow-up: mean 6 months)	34%	39%[4] (30% to 47%)	1.1	4%	310 (1[5])	⊕⊕⊕⊕ **high**[2]	Not statistically significant
Function after intervention Pooled different scales[1]	36%	46% (40% to 52%)	1.3	10%	648 (4[3])	⊕⊕⊕⊕ **high**[2]	8 (5 to 19)
Function follow up WOMAC physical function. Scale from: 0 to 68. (follow-up: mean 6 months)	36%	39% (31% to 48%)	1.1	4%	306 (1[5])	⊕⊕⊕⊕ **high**[2]	Not statistically significant
Harms							
Withdrawals follow up total withdrawals (follow-up: mean 18 months)	29%	35% (25 to 48%)	**RR 1.2** (0.86 to 1.66)	6%	312 (1[5])	⊕⊕⊕⊕ **high**[2]	Not statistically significant
Adherence	Found 59% adherence to aquatic exercise intervention[5].						
Safety	Not reported						

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio;

GRADE Working Group grades of evidence
High quality: Further research is very unlikely to change our confidence in the estimate of effect.
Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

[1] Pooled different scales including WOMAC, VAS, HAQ
[2] Patients not blinded to treatment as it is impossible to do so, therefore we did not downgrade
[3] Cochrane 2005, Foley 2003, Wang 2004, Patrick 2001
[4] This RCT had a significant SMD immediately after intervention
[5] Cochrane 2005

Visual Summary of Findings Table

Aquatic exercise compared to no exercise for osteoarthritis of hip or knee Chance: Improving pain immediately after aquatic exercise	
NNT: 11	
59 people out of 100 don't improve whether or not they did aquatic exercise	
34 people out of 100 improve whether or not they did aquatic exercise	
7 more people out of 100 improve with aquatic exercise	
Chance: Improving pain after 6 months	
NNT: n/a	**Not statistically significant**
61 people out of 100 don't improve whether or not they did aquatic exercise	
34 people out of 100 improve whether or not they did aquatic exercise	
5 more people out of 100 improve with aquatic exercise	
Chance: Improving function immediately after aquatic exercise	
NNT: 8	
54 people out of 100 don't improve whether or not they did aquatic exercise	
36 people out of 100 improve whether or not they did aquatic exercise	
10 more people out of 100 improve with aquatic exercise

1.4 Tai chi

Is tai chi effective in reducing pain and improving function in patients with symptomatic knee OA compared to usual care?

Step 1: Search Results
One systematic review (Lee 2008) assessed the effect of tai chi in patients with both hip and knee OA. However, results of the 5 included RCTs and 7 non-randomized studies were not pooled due to high heterogeneity. Therefore, we chose the RCT from this systematic review which most closely matched our PICO question by having an appropriate control group and with the largest sample size. The RCT by Brismee, 2007 was the closest match to having a control group (defined as "attention control in Brismee 2007) since the other studies had control groups of hydrotherapy, routine care and bingo.

Intervention description: Simplified Yang-style tai chi with instructor three times a week for six weeks followed by six weeks with home video.

Note: the study included has a sample size of 31 people, and 24% of the participants were lost to follow-up.

Step 2: GRADE Summary of findings

	Tai chi compared to no exercise (education on OA) for knee OA						
	Patient or population: patients with osteoarthritis of the knee **Settings:** **Intervention:** tai chi **Comparison:** no exercise (education on OA)						
Outcomes	**Illustrative comparative risks* (95% CI)**		**Relative effect (95% CI)**	**Absolute difference**	**No of Participants (studies)**	**Quality of the evidence (GRADE)**	**NNT**
	Assumed risk **no exercise (education on OA)**	Corresponding risk **Tai chi**					
Benefit							
Pain WOMAC . Scale from: 0 to 35. (follow-up: mean 12 weeks)	33%	35% of those in tai chi group experienced a decrease in pain (11% to 58%)	2%	1.1	31 (1[2])	⊕⊕OO **low**[1]	Not statistically significant

Function WOMAC. Scale from: 0 to 85. (follow-up: mean 12 weeks)	33%	35% (11% to 58%)	2%	1.1	31 (1[2])	⊕⊕OO **low**[1]	Not statistically significant
Harms							
Withdrawals Number of drop-outs (follow-up: mean 12 weeks)	**32%**	**18%** (6 to 55%)	**RR 0.58** (0.19 to 1.74)	13%	41 (1[2])	⊕⊕⊕O **moderate**[1]	Not statistically significant **(Note: more people in the control group withdrew from the study)**
Adherence	90% adherence in tai chi group						
Safety	Not reported						

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio;

GRADE Working Group grades of evidence
High quality: Further research is very unlikely to change our confidence in the estimate of effect.
Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

[1] Large CI and small N=35
[2] Brismee, 2007

Visual Summary of Findings Table

Tai chi compared to no exercise (education on OA) for osteoarthritis of the knee

Chance: Improving pain		
NNT: n/a		**Not statistically significant**
😐	65 people out of 100 don't improve with either treatment.	
🙂	33 people out of 100 improve with either treatment.	
🙂	**2 more people** out of 100 improve with tai chi.	
Chance: Improving function		
NNT: n/a		**Not statistically significant**
😐	65 people out of 100 don't improve with either treatment.	
🙂	33 people out of 100 improve with either treatment.	
🙂	**2 more people** out of 100 improve with tai chi.	
Chance: Withdrawals*		
NNH: n/a		**Not statistically significant (Note: more people in the control group withdrew from the study)**
😐	68 people out of 100 did not leave the study with either treatment.	
☹	18 people out of 100 left the study with either treatment.	
☹	**13 more** people out of 100 left the study in the control group than the tai chi.	
Chance: Safety		
Safety of tai chi was not reported.		
Chance: Adherence		
90% of people in the tai chi group adhered to the program.		

*does not add up to 100 due to rounding

Step 3: GRADE Evidence profile

See Table 1 g: Tai Chi compared to no exercise (education on OA) for knee OA

Step 4: Other recommendations

Group	Recommendation
AAOS (knee only)	We recommend patients with symptomatic OA of the knee be encouraged to participate in low-impact aerobic fitness exercises. Range of motion/flexibility exercises are an option for patients with symptomatic OA of the knee. We suggest quadriceps strengthening for patients with symptomatic OA of the knee.
EULAR	Non-pharmacological treatment of knee OA should include education, *exercise*, appliances (sticks, insoles, knee bracing) and weight reduction.
OARSI	Patients with hip and knee OA should be encouraged to undertake, and continue to undertake, regular aerobic, muscle strengthening and range of motion exercises. For patients with systematic hip OA, exercises in the water can be effective.

Step 5: GRADE Recommendation

1.5 General hip exercise

Is exercise effective in reducing pain and improving function in patients with symptomatic hip osteoarthritis (OA) compared to usual care?

Step 1: Search Results
One meta-analysis (Hernandez-Molina, 2008) was found which pooled land-based, aquatic, and tai chi exercises. The remaining RCTs found which were not included in the meta-analysis did not follow the guideline's inclusion criteria since they were post-operative interventions.

Intervention description: For the pain outcome, the systematic review (SR) included any exercise program of at least 4 weeks duration (Hernandez-Molina, 2008). For the function outcome, "The exercise group performed water and land-based exercise 3 times weekly over a 6-week period immediately prior to surgery. During the first 3 weeks, participants performed 1–2 sets of 8–12 repetitions of single-joint movements while standing in chest-deep, 93°F water. Pool exercises focused on single planar motion of the cervical spine, shoulders, elbows, wrists, hands, hips, knees, and ankles. During weeks 4–6, exercise sessions involved a total body fitness program of cardiovascular, strength, and flexibility training" (Rooks, 2006).

Step 2: GRADE Summary of findings

	exercise compared to no exercise for osteoarthritis of the hip						
	Patient or population: patients with osteoarthritis of the hip **Settings:** **Intervention:** exercise **Comparison:** no exercise						
Outcomes	**Illustrative comparative risks* (95% CI)** Assumed risk **no exercise**	Corresponding risk **exercise**	**Relative effect (95% CI)**	**Absolute difference**	**No of Participants (studies)**	**Quality of the evidence (GRADE)**	**NNT**
Benefit							
Pain pooled WOMAC and VAS . Scale from: 0 to 100. (follow-up: 3-18 months)	34%	56% of those in any exercise group experienced a decrease in pain (38% to 100%)	1.6	22%	310 (7[2])	⊕⊕⊕O **moderate**[1]	4 (2 to 18)
Function	Not reported						
Harms							
Safety	Not reported						

Withdrawals	Not reported
Adherence	Not reported
	*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. 2. INSOLES

2.1 Laterally wedged insoles versus neutrally wedged insoles for knee OA

Are laterally wedged insoles effective in reducing pain and improving function in patients with symptomatic medial compartment knee OA compared to neutrally wedged insoles? Are patients adherent to these treatment regimens?

Step 1: Search Results

We chose Brouwer, 2008 for lateral wedge insoles since it is the most recent and relevant SR (SR). This SR reported only one RCT comparing laterally and neutrally wedged insoles: Maillefert, 2001.

Intervention description: Insoles were made of Ledos material (Société Française d'Orthopodie, Paris, France), mounted on a leather strip. The Ledos material is made of pure rubber with cork powder, and has a great capacity to absorb impact loading. The laterally elevated insoles were individually modeled, with elevation depending on static pedometer evaluation, but without any biomechanical evaluation during walking.

Step 2: GRADE Summary of findings

Laterally wedged insoles compared to neutrally wedged insoles for painful medial knee osteoarthritis

Patient or population: patients with painful medial Knee OA
Intervention: Laterally wedged insoles
Comparison: neutrally wedged insoles

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **neutrally wedged insoles**	Corresponding risk **Laterally wedged insoles**					
Benefits							
Pain WOMAC. Scale from: 0 to 100. (follow-up: 6 months)	35%[1]	25% (16% to 36%)	-10%	0.71	147 (1)	⊕⊕OO low[2,3]	Not statistically significant *Laterally wedged insoles show less improvement in pain than neutrally wedged insoles.
Physical function WOMAC. Scale from: 0 to 100. (follow-up: mean 6 months)	35%[4]	25% (16% to 37%)	-10%	0.71	147 (1)	⊕⊕OO low[2,3]	Not statistically significant *Laterally wedged insoles show less improvement in function than neutrally wedged insoles.
Harms							
Adherence number of patients who wore insoles permanently during the study period (follow-up: 6 months)	74%	88% (75% to 100%)	14%	1.18 (1.01 to 1.38)	156 (1)	⊕⊕⊕O moderate[2]	7 (4 to 135) *Laterally wedged insoles show better compliance than neutrally wedged insoles.
Withdrawals due to intolerance to the treatment number of patients who withdrew from the study because of intolerance to the treatment (follow-up: 6 months)	1%	0% (0% to 10%)	-1%	0.30 (0.01 to 7.28)	156 (1)	⊕⊕OO low[2,3]	Not statistically significant *Laterally wedged insoles show less withdrawals due to intolerance than neutrally wedged insoles.

[1] This SMD was calculated using RevMan 5 with the 6-month end of study data. WOMAC pain was more decreased in the neutrally wedged group than the laterally wedged group. This result along with those at 1, 3, 12 and 24 months is not statistically significant.
[2] The randomization procedure and allocation concealment were not described. The trial (Maillefert, 2001) did not blind the outcome assessors and the care providers. The insoles were individually modeled and therefore the intervention was not identical for all patients. The quality assessment score was not reduced because of this.
[3] The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.
[4] This SMD was calculated using RevMan 5 with the 6-month end of study data. WOMAC function was more decreased in the laterally wedged group than the neutrally wedged group. This result along with those at 1, 3, 12 and 24 months is not statistically significant.

Visual Summary of findings figure:
Laterally wedged insoles compared to neutrally wedged insoles for painful medial Knee OA

Chance: Improving pain and physical function (6 Months)	
NNT: Not statistically significant	Not statistically significant
😐 65 people out of 100 don't improve	
☺ 25 people out of 100 improve either type of insole	
☹ **10 fewer people** out of 100 improve with laterally wedged insoles	
Chance: Adherence (6 months): number of patients who wore insoles permanently during the study period	
NNH: 7	
😐 74 people out of 100 wore either type of insole permanently during the study period.	
☹ 12 people out of 100 did not wear either type of insole permanently during the study period.	
☹ **14 fewer people** out of 100 wore neutrally wedged insoles permanently during the study period.	
Chance: Withdrawing from the trials after 6 months because of intolerance to the treatment.	
NNH: Not statistically significant	**Not statistically significant**
😐 99 out of 100 people did not drop out of the trials	
☹ 0 out of 100 people dropped out with either type of insole	
☹ 1 **more person** out of 100 dropped out with neutrally wedged insoles.	

Step 3: GRADE Evidence profile

See Table 2 a: Laterally wedged insoles versus neutrally wedged insoles

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	We suggest *lateral heel wedges not be prescribed* for patients with symptomatic medial compartmental OA of the knee.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, *insoles*, knee bracing) and weight reduction.
OARSI	Every patient with hip and knee OA should receive advice concerning appropriate footwear. In patients with knee OA, *insoles* can reduce pain and improve ambulation. Lateral wedged insoles can be of symptomatic benefit for some patients with medial tibio-femoral compartment OA.

Step 5: GRADE Recommendation

References

2.2 Medial wedged insoles versus neutrally wedged insoles for knee OA

Are medial wedged insoles effective in reducing pain and improving function in patients with symptomatic lateral compartment knee OA compared to neutrally wedged insoles?

Step 1: Search Results

We chose Rodrigues, 2008 for medial wedged insoles since it is the only RCT we found in the literature review and no SRs have been done on the subject.

Intervention description: The medial insole group wore 8-mm-high medial-wedge insoles for the rearfoot inserted into a new shoe for 8 weeks. The neutral insole group wore an insole resembling that of the former group but without raised wedges for 8 weeks. Patients of both groups received the same new shoe and were blind to insole use. The ethylene-vinyl-acetate (density 50) insoles were provided by the AACD Institute (Associaçao de Assistência à Criança Deficiente). A commercial neoprene with elastic banding was used for ankle support. Both groups used similar standard shoes supplied by the hospital. Each participant was instructed to use the splints (shoes and elastic banding) for 3–6 hours daily.

Step 2: GRADE Summary of findings

*This study has a very small sample size (n=30), which could undermine its validity.

Medially wedged insoles compared to neutrally wedged insoles for knee OA

Patient or population: patients with knee OA
Intervention: Medially wedged insoles
Comparison: neutrally wedged insoles

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk neutrally wedged insoles	Corresponding risk Medially wedged insoles					
Benefits							
Pain on movement VAS scale transformed into percentage of change over time. Scale from: 0 to 100. (follow-up: 8 weeks)	41%	85% (60% to 97%)[1]	44%	2.07	30 (1)	⊕⊕⊕O moderate[2]	3 (2 to 5)
Function WOMAC transformed into percentage of change over time. Scale from: 0 to 100. (follow-up: 8 weeks)	27%	86% (59% to 97%)[1]	59%	3.19	30 (1)	⊕⊕⊕O moderate[2]	2 (2 to 3)
Harms							
Mild discomfort number of patients with event (follow-up: 8 weeks)	7%	2% (0% to 47%)	-5%	0.29 (0.01 to 6.69)	30 (1)	⊕⊕OO low[2,3]	Not statistically significant
Adherence	All patients used the insoles regularly throughout the study						
Withdrawals	No withdrawals						

[1] This SMD was calculated using RevMan 5 with the percentage of change over time provided by the authors.
[2] The sample is small: 30 women with valgus knee OA. Pain at rest was statistically different at baseline.
[3] The confidence interval ranges from not being clinically significant to a very large clinical effect, which shows imprecision.

Visual Summary of findings figure:
Medially wedged insoles compared to neutrally wedged insoles for knee OA

Chance: Improving pain when moving after 8 weeks	
NNT: 3	
15 people out of 100 don't improve with either type of insole	
41 people out of 100 improve with either type of insole	
44 more people out of 100 improve with Medially wedged insoles	
Chance: Improving function after 8 weeks	
NNT: 2	
14 people out of 100 don't improve with either type of insole	
27 people out of 100 improve with either type of insole	
59 more people out of 100 improve with Medially wedged insoles	
Chance: Mild discomfort after 8 weeks	
NNH: n/a	**Not significantly significant**
93 people out of 100 avoid mild discomfort with either type of insole.	
2 people out of 100 have mild discomfort with either type of insole.	
5 more people out of 100 have mild discomfort with neutrally wedged insoles	
Chance: Adherence	
All patients used the insoles regularly throughout the study	
Chance: Withdrawls	
There were no withdrawals from the study	

Step 3: GRADE Evidence profile
See Table 2 b: Medial wedged insoles versus neutrally wedged insoles for knee osteoarthritis

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	We suggest *lateral heel wedges not be prescribed* for patients with symptomatic medial compartmental OA of the knee.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, *insoles*, knee bracing) and weight reduction.
OARSI	Every patient with hip and knee OA should receive advice concerning appropriate footwear. In patients with knee OA, *insoles* can reduce pain and improve ambulation. Lateral wedged insoles can be of symptomatic benefit for some patients with medial tibio-femoral compartment OA.

Step 5: GRADE Recommendation

2.3. Subtalar strapped insoles versus inserted laterally wedged insoles for knee OA

Are subtalar strapped insoles effective in reducing pain and improving function in patients with symptomatic knee OA compared to inserted laterally wedged insoles?

Step 1: Search Results

We chose the SR by Brouwer 2008 which reported one RCT which can be found in three articles by Toda (RCT published in 2001 with follow-up data published in 2004 and 2006). We are presenting the data at 6 months follow-up for efficacy and at 8 weeks for side effects as these were the only time points at which these were evaluated respectively.

Intervention description: Radiographs were evaluated for changes characteristic of OA in anteroposterior views using the Kellgren-Lawrence grade, as described in the *Atlas of Standard Radiographs*. Two types of lateral wedge insoles were prepared: urethane wedges made from household bath mat material with elevations of 6.35 mm strapped to an ankle sprain supporter (Sofra Wolfer®, Taketora Co. Ltd., Japan) designed to fit around the ankle and subtalar joints (strapped insole, Figure 1A); and a traditional inserted insole (Wedge Heel Type®, Sanshinkousan Co. Ltd., Japan), a lateral rubber heel wedge with an elevation of 6.35 mm (inserted insole, Figure 1B). Each participant

was instructed to use the insole whenever wearing shoes, for between 3 and 6 hours each day for 8 weeks.

Step 2: GRADE Summary of findings

Subtalar strapped insoles compared to inserted laterally wedged insoles for knee OA

Patient or population: patients with knee OA
Intervention: Subtalar strapped insoles
Comparison: inserted laterally wedged insoles

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **Inserted laterally wedged insoles**	Corresponding risk **Subtalar strapped insoles**					
Benefits							
Pain visual analog scale. Scale from: 0 to 100. (follow-up: 6 months)	36%	58% (38% to 76%)[1]	22%	1.61	61 (1)	⊕⊕⊕O moderate[2]	4 (3 to 35)
Function Lequesne index (follow-up: 6 months)	37%	48% (29% to 67%)[3]	11%	1.30	61 (1)	⊕⊕⊕O moderate[2]	Not statistically significant
Harms							
Side effects number of patients with event (follow-up: 8 weeks)	2%	13% (2% to 100%)[4]	11%	5.74 (0.72 to 45.77)	90 (1)	⊕⊕OO LOW[2,6]	Not statistically significant
Withdrawals number of patients who withdrew after randomization (follow-up: 6 months)	6%	9% (2% to 53%)[5]	3%	1.59 (0.28 to 8.93)	66 (1)	⊕⊕OO LOW[2,6]	Not statistically significant
Adherence				Not reported			

[1] This SMD was calculated using Rev Man 5 with the 6-months end of study data. This result along with the one at 8 weeks are statistically significant (SMD= -0.42 (-0.83, 0)). The data at 24 month were not statistically significant.
[2] The randomization procedure was done according to birth date and the allocation concealment was not described. The trials (Toda, 2001, 2004 and 2006) did not blind the outcome assessors, the care providers or the patients.
[3] This SMD was calculated using Rev Man 5 with the 6-months end of study data. This result along with the one at 8 weeks and 24 months are not statistically significant.
[4] In the strapped insole group, 3 participants complained of popliteal pain, 2 reported low back pain and one had foot sole pain. Only one patient complained of foot sole pain in the inserted insole group. However, side effects were not severe enough to deter participants from continuing to wear the insole.
[5] People who withdrew had either moved or cited household commitments.
[6] The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.

Visual Summary of findings figure:
Subtalar strapped insoles compared to inserted laterally wedged insoles for knee OA

Chance: Improving pain after 6 Months	
NNT: 4	
42 people out of 100 don't improve with either type of insole

TABLE 1. Lower Extremity Kinesthesia and Balance Exercises Used in the Study

1. Week	1. Modified Romberg exercise (standing in balance with eyes closed)
	a) On hard ground
	b) On soft ground (on a mat)
	2. Retrowalking (25 m)
	3. Walking on heels (25 m)
	4. Walking on toes (25 m)
	5. Walking with eyes closed (25 m)
	6. Standing on one extremity for 30 seconds (repeated in both extremities)
	Leaning forward, backward, and to the sides on one extremity (eyes open)
	Leaning forward, backward, and to the sides on one extremity (eyes closed)
	Sitting down and standing up from a high chair slowly
2. Week (in addition)	1. Exercise with "rocker-bottom" balance board
	2. Sitting down and standing up from a low chair slowly
	3. Plyometric exercise (crossing a height of 15 cm by jumping)
	4. 8 exercise
	a) Walking slowly, wide circle
	b) Walking quickly, wide circle
	c) Walking slowly, narrow circle
	d) Walking quickly, narrow circle
3. Week (in addition)	1. Exercise with "BAPS board" balance board
	a) Balance with 2 legs, eyes open, multidirectional
	b) Balance with 2 legs, eyes closed, multidimensional
	c) Balance with one leg, eyes open, unidimensional
	d) Balance with one leg, eyes closed, unidimensional
	e) Balance with one leg, eyes open, multidimensional
	f) Balance with one leg, eyes closed, multidimensional
	2. Minitrampoline exercise (jumping and jogging)
	3. Plyometric exercise (crossing a height of 15 cm by jumping)
	4. Carioca crossover maneuver

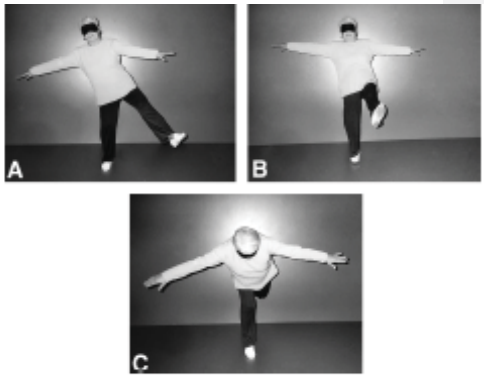

FIGURE 1. (A) Balance exercise toward the sides on a single foot while the eyes are closed. (B) Balance exercise toward the back on a single foot while the eyes are closed. (C) Balance exercise toward the front on a single foot while the eyes are closed.

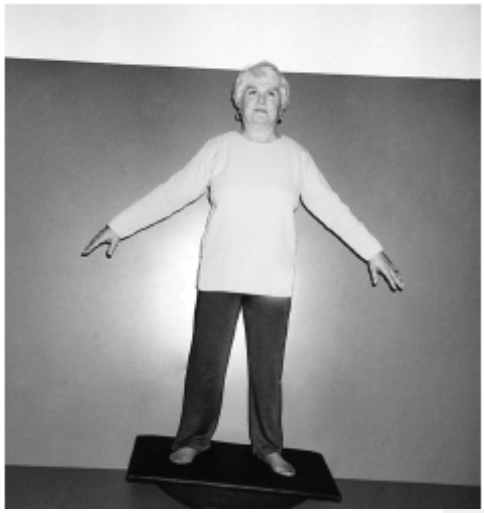

TABLE 2. Lower Extremity Isometric and Isotonic Strengthening Program Used in the Study

1. Week	1. 5-min fixed bike exercise without resistance
	2. Range-of-motion and active stretching exercises applied to hamstring and quadriceps muscles
	3. Quadriceps isometric strengthening exercise
	4. Hamstring muscles isometric exercise
2. Week (in addition)	1. Short-arc terminal extension exercise for the knee joint
	2. Isometric exercise for the abductor and adductor muscles of the hip joint
3. Week (in addition)	1. Short-arc terminal extension exercise with resistance for the knee joint
	2. Isometric strenghtening exercise with resistance for the hamstring muscles

3. SELF-MANAGEMENT

Are self-management programs effective in reducing pain and improving function in patients with symptomatic knee osteoarthritis (OA) compared to usual care?

Step 1: Search Results
Three meta-analyses on self-management programs were found (Chodosh, 2005; Devos-Comby, 2006; Warsi, 2004). Although Devos-Comby (2006) was the most recent evidence, exercise and self-management were presented such that outcomes from each intervention could not be separated. Warsi (2004) did not focus on OA. Chodosh (2005) met our selection criteria and was therefore chosen as the best available evidence. Devos-Comby (2006) had similar results to Chodosh (2005), whereby, no clinically significant effect was found on physical outcomes.

Interventions description: Chronic disease self-management program was defined by the authors of the systematic review as "a systematic intervention that is targeted toward patients with chronic disease. The intervention should help them actively participate in either or both of the following: self-monitoring (of symptoms or of physiologic processes) or decision making (managing the disease or its impact through self-monitoring)" (Chodosh, 2005).

Step 2: GRADE Summary of findings

Self-management program compared to no self-management for knee OA

Patient or population: patients with Osteoarthritis
Intervention: Self-management program
Comparison: no self-management

Outcomes	Illustrative comparative risks* (95% CI) Assumed risk no self-management	Corresponding risk Self-management program	Relative effect (95% CI)	Absolute difference	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
Benefit							
pain Not specified but likely pooled several different scales (follow-up: 2-6 months)	41%	43% of those in self-management program group experienced a decrease in pain (41% to 44%)	1.05	2%	Not available	⊕⊕OO LOW	36 (22 to 108)
function Not specified but likely pooled several different scales (follow-up: 2-6 months)	31%	33% (31% to 34%)	1.06	2%	Not available	⊕⊕OO LOW	34 (21 to 103)
Harms							
safety			Not reported				
adherence			Not reported				
withdrawals			Not reported				

NOTE 1: *Although we acknowledge that psychological outcomes are relevant to self-management interventions, we decided a priori to focus only on effects on pain and function outcomes. Chodosh (2005) did not report any psychological outcomes. Devos-Comby (2006) found that although psychological outcomes were significantly improved, perceived psychological health was not statistically different.*

NOTE 2: *There was a rigorous exchange of ideas between Drs. Holman and Lorig and the authors of Chodosh (2005). The conclusion was that increased evidence is needed on the different types of self-management programs as well as long term data. This exchange can be found at* http://www.annals.org/cgi/content/abstract/143/6/427

Visual Summary of Findings Table
Self-management program compared to no self-management for osteoarthritis

Chance: Improving pain after 8 weeks	
NNT: 6	
57 people out of 100 don't improve whether they take a self management program or not	
41 people out of 100 improve with either intervention	
2 more people out of 100 improve with a self-management program	
Chance: Improving function after 8 weeks	
NNT: 6	
67 people out of 100 don't improve whether they take a self management program or not	
31 people out of 100 improve with either intervention	
2 more people out of 100 improve with a self-management program	
Chance: Safety, Adherence, Withdrawals	
NNH: n/a The safety of self-management and the number of people who adhered to a self-management program and the number of people who withdrew from self management programs was not reported.	**Not reported**

Step 3: GRADE Evidence profile
See Table 3: Self-management

NOTE: Post-hoc tests including 5 essential elements (tailoring, group setting, feedback, psychological, and medical care) were unrevealing.

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	• We suggest patients with symptomatic OA of the knee be encouraged to participate in self-management educational programs such as those conducted by the Arthritis Foundation, and incorporate activity modifications (e.g. walking instead of running; alternative activities) into their lifestyle. • Regular contact to promote self-care is an option for patients with symptomatic OA of the knee. (No recommendations for hip).
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, knee bracing) and weight reduction.
OARSI	• Optimal management of OA requires a combination of non-pharmacological and pharmacological modalities. • All patients with hip and knee OA should be given information access and education about the objectives of treatment and the importance of changes in lifestyle, exercise, pacing of activities, weight reduction, and other measures to unload the damaged joint(s). The initial focus should be on self-help and patient-driven treatments rather than on passive therapies delivered by health professionals. Subsequently emphasis should be placed on encouraging adherence to the regimen of non-pharmacological therapy. • The clinical status of patients with hip or knee OA can be improved if patients are contacted regularly by phone.

Step 5: GRADE Recommendation

4. MANUAL THERAPY

4.1 Manual therapy program versus exercise therapy program for hip OA

Is manual therapy effective in reducing pain and improving function in patients with symptomatic hip osteoarthritis (OA) compared to exercise therapy? Are patients compliant to these treatment regimens and do they experience adverse effects?

Step 1: Search Results
There were no meta-analyses which reported the efficacy of manual therapy in patients with hip OA. There was one RCT which assessed the efficacy of manual therapy vs. exercise therapy in patients with hip OA: Hoeksma (2004).

Intervention description: Subjects in both the manual therapy program and the exercise therapy program attended 25-minute sessions twice a week for a total of 9 treatments. Manual therapy consists of manipulation and stretching with the aim of improving the elasticity of the joint capsule and surrounding muscles. Each manual therapy session began with 10 to 15 minutes of stretching of shortened muscles. Manipulation was then performed using a traction manipulation technique.
The exercise therapy program was tailored to each individual participant's needs. The 4 main treatment goals were 1) increase of muscle function through muscle strengthening exercises using weight or strengthening equipment; endurance by treadmill walking of cycling on a home trainer; and coordination by walking and balancing exercises; 2) improvement of range of joint motion by motions that go beyond the daily activity range of motion and stretching; 3) decrease of pain through active joint and stretching exercises as well as second and third degree traction; 4) improvement of walking ability through specific walking exercises to adjust gait pattern, use of walking aids, and stair-climbing instruction.

In both groups, participants also received education and advice on the load ability of the hip joint and increasing their physical activity. The exercise group received additional instruction for home exercise, based on the specific exercises performed during the treatment session.

Further details about the treatment programs are described on the pages following the results.

Step 2: GRADE Summary of findings

Manual therapy compared to exercise therapy for hip OA

Patient or population: patients with hip OA
Intervention: manual therapy
Comparison: exercise therapy

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **exercise therapy**	Corresponding risk **manual therapy**					
Benefits							
Pain at rest VAS. Scale from: 0 to 100. Follow-up: 5 weeks	35%	54% (38% to 69%)[1]	19%	1.54	103 (1 study)	⊕⊕⊕⊕ high[2]	5 (3 to 27)
Physical function SF-36 Scale from: 0 to 100. Follow-up: 5 weeks	35%	39% (26% to 55%)[1]	4%	1.11	103 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Pain at rest VAS. Scale from: 0 to 100. Follow-up: 29 weeks	40%	50% (34% to 66%)[4]	10%	1.25	89 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Physical function SF-36 Scale from: 0 to 100. Follow-up: 29 weeks	35%	45% (29% to 62%)[4]	10%	1.29	88 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Harms							
Lack of adherence number of patients who prematurely discontinued the treatment programs Follow-up: 5 weeks	6%	7% (2% to 31%)	1%	1.26 (0.30 to 5.37)	109 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Adverse effects number of patients who discontinued the treatment programs because of increase of complaints[5]	4%	5% (1% to 31%)	1%	1.42 (0.25 to 8.16)	109 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant
Losses to follow-up number of patients who were lost to follow-up Follow-up: 29 weeks	17%	21% (10% to 47%)	4%	1.26 (0.58 to 2.75)	109 (1 study)	⊕⊕⊕O moderate[2,3]	Not statistically significant

[1] This SMD was calculated with RevMan 5 with the end-of-study data at the end of the treatment period (5-weeks).

[2] This trial was a single-blind study. The authors mention that it was not possible to blind either patients or therapists for the allocated treatment. Therefore, extra attention was given to the blinding of the outcome assessor. A placebo effect may also be present in this study due to the nature of the interventions. Finally, a limitation of the study is the relatively large number of patients who received total hip arthroplasty during the follow-up period. However, no significant differences were found between the conclusions based on the intention-to-treat analysis and the per-protocol analysis. The quality of the study was not downgraded because of these reasons.
[3]The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.
[4] This SMD was calculated with RevMan 5 with the end-of-study data at 29 weeks of follow-up.
[5] In the exercise program, one patient also discontinued treatment because of cardiorespiratory disease.

Visual Summary of Findings Table
Manual therapy compared to exercise therapy for hip OA

APPENDIX A: MANUAL THERAPY IN OSTEOARTHRITIS OF THE HIP: A PROTOCOL

Developed by the Department of Physical Therapy, Leyenburg Hospital and the Netherlands Institute for Health Services Research

Frequency of sessions and duration of episode

The duration of a session is 25 minutes. The frequency is twice a week at a total of 9 treatments.

Treatment protocol

Manual therapy (manipulation and stretching) is particularly aimed at the improvement of elasticity of the joint capsule and the surrounding muscles.

Muscle stretching. Muscle stretching is an integrated part of the manual therapy program. Each session starts with stretching of shortened muscles. The following muscle (groups) are stretched: m. iliopsoas, m. quadriceps femoris, m. tensor fascia latae, m. sartorius, m.m. adductors and m. gracilis (1). Starting posture is a supine position. The patient has to experience a stretching sensation. Actual stretching is applied for 8 to 10 seconds. Repeat stretching of each muscle (group) 2 times. Total time: 10–15 minutes.

Manipulation. Manipulation is performed according to a traction manipulation technique (2). The therapist's hands are placed just above the ankle joint. All manipulations are performed in slight abduction to avoid slamming of the femoral head into the acetabular surface. The first traction manipulation is performed in the maximum loosed packed position of the hip joint (2). With each following manipulation, the hip joint is placed in a more limited position (which differs per patient). In total, a maximum of 5 manipulations can be applied. The final manipulation is performed in the most limited position of the hip joint. In between manipulations, active assisted motions of the hip joint are performed for relaxation.

To evaluate the success of manipulation, after each manipulation "end feel" of the hip joint is tested using a

traction test and by passive hip flexion. This is compared with the contralateral hip. When end feel of the treated hip is similar to the contralateral hip, optimal result is concluded.

Patient education and advice. The promotion of physical activities in general is of importance. Main goal is to couple improvement in joint function with physical activities, such as walking, cycling, and swimming. Furthermore, instruction about load ability of the hip joint has to be provided.

APPENDIX B: EXERCISE THERAPY IN OSTEOARTHRITIS OF THE HIP: A PROTOCOL

Developed by the Department of Physical Therapy, Leyenburg Hospital and the Netherlands Institute for Health Services Research

Introduction

This is a summary of the exercise protocol. The protocol is an adaptation of the protocol of Van Baar et al (1). In addition, the book of Evjenth and Hamberg is followed on muscle stretching techniques (2). All participating physical therapists are instructed in training sessions. These training sessions will be repeated every 3 months.

Frequency of sessions and duration of episode

The duration of a session is 25 minutes. The frequency is twice a week at a total of 9 treatments.

Treatment protocol

The exercise program is tailored to the individual patient's needs by the therapist. The first session is used to compile exercise therapy treatment goals by questioning, physical examination, and observation of walking ability. It is of great importance to identify specific impairments and disabilities that are of high priority to the patient.

There are 4 main treatment goals on which exercise therapy focuses: 1) increase of muscle function, including endurance, strength, and coordination; 2) improvement of range of motion; 3) decrease of pain; and 4) improvement of walking ability. Furthermore, education and advice need to be provided to the patient.

Muscle function. Mainly active exercises have to be applied to improve muscle function. Exercises consist of muscle strengthening exercises with the use of weight or strengthening equipment. Endurance is trained by walking on a treadmill or cycling on a home trainer. Finally, coordination is trained through walking exercises with increased complexity and through balancing exercises.

Range of motion. If regarded necessary, range of joint motion can be increased through both passive and active exercises. Active exercises should have the upper hand.

Active exercises consist of 3-dimensional motions of the hip joint that go beyond the range of joint motion that most patients use in activities of daily living. These exercises can be performed in weight-bearing and non–weight-bearing positions. In addition, these exercises can be applied in different positions, such as during standing, sitting on a chair, and while lying down.

Passive exercises contain passive movement of the hip and stretching exercises according to Evjenth and Hamberg. Postures and starting positions for stretching exercises can be found in the book of Evjenth and Hamberg (2).

Pain. If regarded necessary, exercises for pain relief can be applied. Pain relief is also achieved through active joint motion exercises and through stretching exercises. In addition, second and third degree traction in the maximum loosed packed position of the hip can be applied (2).

Walking ability. Walking ability is trained by specific walking exercises with adjustment of gait pattern, use of walking aids, and instruction on climbing of stairs.

Patient education, advice, and home exercises. The promotion of exercise in general is of great importance; such activities as walking, cycling, and swimming are recommended. Concerning home management and social activities, these are specifically focused to take an active approach to pain, instead of taking rest and sitting down. Avoidance of prolonged static load and instruction on load ability of the hip should be emphasized. Instructions for home exercises, derived from the specific exercises as performed during the treatment sessions, are provided.

4.2 Manual therapy in combination with supervised exercise and home exercise program versus home exercise program alone for knee OA

Is individualized manual therapy in combination with supervised exercise and home exercise program effective in reducing pain and improving function in patients with symptomatic knee OA compared to home exercise program? Are patients compliant to these treatment regimens?

Step 1: Search Results

There were no meta-analyses which reported the efficacy of manual therapy in patients with knee OA. A few RCTs assessed the efficacy of manual therapy specifically in patients with knee OA but most had limitations (sample size smaller than 50 participants) or used manual therapy in combination with other modalities such as taping and massage, making it difficult to evaluate its efficacy. We chose the only RCT conducted in patients with knee OA which assessed the efficacy of manual therapy in combination with supervised exercises, the treatment combination deemed the most used in clinical practice by our team of experts: Deyle (2005). We contacted the authors in order to report results for the pain and function subscales of the WOMAC since only the total WOMAC score was reported in their publication. The treatment programs used in this study are described following the results.

Intervention description: Subjects in the clinic treatment group attended 8 treatment sessions over a 4 week period in the physical therapy clinic. Manual therapy programs were individualized based on the results of the examination. The manual therapy techniques, consisting of passive physiological and accessory movements, muscle stretching, and soft tissue mobilization, were applied by the treating physical therapist primarily to the knee and surrounding structures. In addition to receiving manual therapy treatments, subjects in the clinic treatment group performed a standardized knee exercise program at each treatment session. This program consisted of active ROM exercises, muscle strengthening, muscle stretching, and riding a stationary bicycle. A physical therapist or physical therapy technician supervised these exercises. The number of strengthening exercise bouts and stationary bicycle riding time were increased or decreased by the treating physical therapist based on subject response. Subjects in the clinic treatment group performed the same home exercise program as the home exercise group each day that they were not treated in the physical therapy clinic.

Step 2: GRADE Summary of findings

Manual therapy in combination with supervised exercise and home exercise program compared to home exercise for knee OA

Patient or population: patients with knee OA
Intervention: manual therapy in combination with supervised exercise and home exercise program
Comparison: home exercise

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **Home exercise**	Corresponding risk **Manual therapy + supervised exercise and home exercise program**					
Benefits							
Pain WOMAC. Scale from: 0 to 500. Follow-up: 8 weeks	37%	53% (39% to 67%)	16%	1.43	120 (1 study[2])	⊕⊕⊕⊕ high[1]	6 (3 to 43)
Function WOMAC. Scale from: 0 to 1700. Follow-up: 8 weeks	37%	52% (38% to 66%)	15%	1.41	120 (1 study)	⊕⊕⊕⊕ high	6 (3 to 70)
Harms							
Safety				**Not reported**			
Discontinuations due to lack of adherence number of patients who discontinued due to lack of adherence to the treatment regimen (whether subjects attended all clinical appointments and reported for testing at 0, 4 and 8 weeks). Follow-up: 8 weeks	0%	0%	0%	0	120 (1 study)	⊕⊕⊕⊕ high	Not statistically significant
Withdrawals people who withdrew from the study after randomization. Follow-up: 8 weeks	12 %[3]	9% (3% to 25%)[4]	-3%	0.77 (0.28 to 2.11)	134 (1 study)	⊕⊕⊕O moderate[5]	Not statistically significant

[1] The authors report that the intention to treat results with 134 subjects did not differ substantially from the results of the 120 subjects.
[2] Another outcome reported by the author was the use of medications for OA by patients at 52 weeks. Use of medications for OA was higher in the home exercise group (68%) than the clinic treatment group (48%) and this difference was statistically significant (p=0.03).
[3] In the control group, withdrawals were due to: knee injections (1), changed medications (1), shoulder surgery (1), not willing to return (2) and moved from area (3).
[4] In the treatment group, withdrawals were due to: knee injections (2), changed medications (1), not willing to return (1), not willing to walk (1) and unrelated medical condition (1).
[5] The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.

Visual Summary of Findings Table
Manual therapy in combination with supervised exercise and home exercise program compared to home exercise for knee OA

Chance: Improving pain after 8 weeks

Step 3: GRADE Evidence profile

See Table 4 b: Manual therapy in combination with supervised exercise and home exercise program versus home exercise program alone for knee OA

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	No recommendations for manual therapy.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, *insoles*, knee bracing) and weight reduction.
OARSI	Optimal management of OA requires a combination of non-pharmacological and pharmacological modalities.

Step 5: GRADE Recommendation

References

Deyle GD, Allison SC, Matekel RL et al. Physical therapy treatment effectiveness for osteoarthritis of the knee: a randomized comparison of supervised clinical exercise and manual therapy procedures versus a home exercise program. Phys Ther 2005;85(12):1301-17.

Description of the treatment programs:

Subjects in the clinic treatment group attended 8 treatment sessions over a 4 week period in the physical therapy clinic. Manual therapy programs were individualized based on the results of the examination. The manual therapy techniques, consisting of passive physiological and accessory movements, muscle stretching, and soft tissue mobilization, were applied by the treating physical therapist primarily to the knee and surrounding structures. In addition to receiving manual therapy treatments, subjects in the clinic treatment group performed a standardized knee exercise program at each treatment session. This program consisted of active ROM exercises, muscle strengthening, muscle stretching, and riding a stationary bicycle. A physical therapist or physical therapy technician supervised these exercises. The number of strengthening exercise bouts and stationary bicycle riding time were increased or decreased by the treating physical therapist based on subject response. Subjects in the clinic treatment group performed the

same home exercise program as the home exercise group each day that they were not treated in the physical therapy clinic.

The home exercise group received detailed verbal and hands-on instruction in a home-based program of the same exercises as the clinical treatment group. Similar to the subjects who received clinical treatment, subjects in the home exercise group were instructed that pain should be avoided in all exercises except in the case that pain or stiffness decreased with each repetition. Each subject received a detailed supporting handout containing instructions and photographs of the exercises. Subjects in the home exercise group were allowed to ride a stationary bicycle if they stated that riding a bicycle was currently part of their exercise routine or if they could not walk for safety reasons. A follow-up examination was performed for the home exercise group 2 weeks after the initial visit.

Table 1.
Comparison of Interventions by Intervention Group

Clinical Treatment Group Interventions	Performance	Home Exercise Group Interventions	Performance
Strengthening exercise	Clinic and home	Strengthening exercise	Home
Stretching exercise		Stretching exercise	
ROM exercise		ROM exercise	
Stationary bicycle[a]		Stationary bicycle[a]	
Manual therapy	Clinic	No manual therapy	
Level of exercise supervision and instruction	1 exercise instruction session 7 supervised exercise sessions	Level of exercise supervision and instruction	2 exercise instruction sessions

[a] Home stationary bicycle riding in both exercise groups was allowed if it was part of the participant's exercise program before the study. Participants in the home exercise group were not specifically instructed to ride a stationary bicycle, nor was it recorded on the exercise adherence log. ROM=range of motion.

5. PSYCHOSOCIAL INTERVENTIONS

Are psychosocial interventions effective in reducing pain and improving function in patients with symptomatic knee OA compared to usual care?

Step 1: Search Results
The chosen evidence (Dixon, 2007) constitutes the best and most recent meta-analysis found, although it pooled different psychosocial therapies without separating cognitive behavioural therapy, which constituted 70% of the interventions in the meta-analysis and did not separate patients with knee or hip OA. Other SRs were older and did not contain necessary data.

Intervention description: Program consisting of three phases: (1) education of patient; (2) skills-training in cognitive-behavioural coping skills; and (3) application to real-life situations. These are usually administered by health care professionals.

Step 2: GRADE Summary of findings

psychosocial intervention compared to no intervention for osteoarthritis of the hip and knee

Patient or population: patients with osteoarthritis of the hip and knee
Settings:
Intervention: psychosocial intervention
Comparison: no intervention

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	Absolute difference	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **no intervention**	Corresponding risk **psychosocial intervention**					
Benefits							
pain pooled different scales including AIMS and VAS (follow-up: 2-12 months)	41%	49% of those psychosocial intervention group experienced a decrease in pain (45% to 54%)	1.19	8%	1483 (8)	⊕⊕OO **low**[1,2]	10 (7 to 20)
Function (physical disability) (follow-up: 2-12 months)	41%	48% of those psychosocial intervention group experienced an increase in function (43% to 52)	1.17	7%	1483 (8^{2})	⊕⊕OO **low**[1,3]	12 (8 to 36)
Harms							
Safety	Not reported						
Withdrawals	Not reported						
Adherence	Not reported						

*The basis for the **assumed risk** (e.g. the median control group risk across studies) is provided in footnotes. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval;

GRADE Working Group grades of evidence
High quality: Further research is very unlikely to change our confidence in the estimate of effect.
Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is

likely to change the estimate.
Very low quality: We are very uncertain about the estimate.

[1] Pooled wide range of psychosocial interventions
[2] Affected joints not described therefore could not distinguish between hip, knee, and other.
[3] No description of type of scales used.

Visual Summary of Findings Table
Psychosocial intervention compared to no intervention for osteoarthritis of the hip and knee

Chance: Improving pain after 2-12 months	
NNT: 10	
😐	51 people out of 100 don't improve whether or not they take part in a psychosocial intervention.
☺	41 people out of 100 improve whether or not they take part in a psychosocial intervention.
☺	**8 more people** out of 100 improve with a psychosocial intervention.
Chance: Improving function after 2-12 months	
NNT: 12	
😐	52 people out of 100 don't improve whether or not they take part in a psychosocial intervention.
☺	41 people out of 100 improve whether or not they take part in a psychosocial intervention.
☺	**7 more people** out of 100 improve with a psychosocial intervention.
Chance: Withdrawls	
The number of people who left the study was not reported.	
Chance: Safety	
Safety of psychosocial interventions was not reported.	
Chance: Adherence	
Adherence to psychosocial interventions was not reported.	

Step 3: GRADE Evidence profile
See Table 5: Psychosocial intervention compared to no intervention for OA of the hip and knee

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	We suggest patients with symptomatic OA of the knee be encouraged to participate in self-management educational programs such as those conducted by the Arthritis Foundation, and incorporate activity modifications (e.g., walking instead of running; alternative activities) into their lifestyle.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, knee bracing) and weight reduction.
OARSI	Optimal management of OA requires a combination of non-pharmacological and pharmacological modalities. 2. All patients with hip and knee OA should be given information access and education about the objectives of treatment and the importance of changes in lifestyle, exercise, pacing of activities, weight reduction, and other measures to unload the damaged joint(s). The initial focus should be on self-help and patient-driven treatments rather than on passive therapies delivered by health professionals. Subsequently emphasis should be placed on encouraging adherence to the regimen of non-pharmacological therapy.

Step 5: GRADE Recommendation

6. WEIGHT LOSS

Is weight loss effective in reducing pain and improving function in patients with symptomatic knee OA compared to usual care and sham acupuncture?

Step 1: Search Results
We found one meta-analysis (Christensen, 2007), which pooled the results from 4 randomized controlled trials (Christensen, 2005; Messier, 2000; Messier, 2004; Toda, 1998). Toda, 1998 results were not included in this summary of findings due to the use of pharmacological intervention to achieve weight loss. [The 8 remaining publications found were single randomized controlled trials (RCTs) and were not included. These were either already included in the meta-analysis (2), did not fall under the inclusion criteria (2) or were written in a language other than English (2). It is uncertain why 2 RCTs (Fotch 2005 and Miller 2006) were not included in the meta-analysis; it is suggested thatthese RCTs were indexed after the search performed in 2006. All of the additional RCTs findings were in the same direction as those of Christensen 2007.]

Interventions description: interventions included were weight loss interventions using CBT, nutrition, and/or exercise approaches and excluded pharmacological interventions

Step 2: GRADE Summary of findings

weight loss compared to control (no weight loss program) for knee OA

Patient or population: patients with knee osteoarthritis
Settings:
Intervention: weight loss
Comparison: control (no weight loss program)

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	Absolute difference	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **Control (no weight loss)**	Corresponding risk **Weight loss**					
Benefits							
pain WOMAC 500mm. Scale from: 0 to 500. (follow-up: 8-24 weeks)	36%	44% of those in weight loss group experienced a decrease in pain (37% to 52%)	1.2	7.8%	416 (2^{2})	⊕⊕⊕O **moderate**[1]	11 (not estimable)
function WOMAC 1700mm. Scale from: 0 to 1700.	34%	43% (36% to 50%)	1.26	9%	416 (2^{2})	⊕⊕⊕O **moderate**[1]	9 (5 to 52)

(follow-up: mean 8-24 weeks)	
	Harms – no harms were reported

😐 57 people out of 100 don't improve with or without a weight loss program	
☺ 34 people out of 100 improve with or without participating in a weight loss program	
☺ **9 more people** out of 100 improve with participation in a weight loss program	
Chance: Harms	
Safety, adherence and the number of people who withdrew were not reported in the SR.	

Step 3: GRADE Evidence profile
See Table 6: Weight loss compared to control (no weight loss program) for knee OA

Step 4: Other recommendations

Group	Recommendation
AAOS - knee	We recommend patients with symptomatic OA of the knee, who are overweight (as defined by a BMI>25), should be encouraged to lose weight (a minimum of five percent (5%) of body weight) and maintain their weight at a lower level with an appropriate program of dietary modification and exercise.
EULAR - knee	Non-pharmacological treatment of knee OA should include regular education, exercise, appliances (sticks, insoles) and weight reduction if obese or overweight.
EULAR – hip	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, knee bracing) and weight reduction.
OARSI	All patients with hip and knee OA should be given information access and education about the objectives of treatment and the importance of changes in lifestyle, exercise, pacing of activities**, weight reduction,** and other measures to unload the damaged joint(s). The initial focus should be on self-help and patient-driven treatments rather than on passive therapies delivered by health professionals. Subsequently emphasis should be placed on encouraging adherence to the regimen of non-pharmacological therapy.

Step 5: GRADE Recommendation

7. BRACES

7.1 Braces and medical (conservative) treatment versus medical (conservative) treatment in knee OA

Are braces and conservative treatment effective in reducing pain and improving function in patients with symptomatic uni-compartmental knee osteoarthritis (OA) and a mal-alignment compared to conservative treatment alone?

Step 1: Search Results
The most recent systematic review (SR) was the one by Brouwer, 2008 which reported one RCT conducted by the same author in 2006 and one by Kirkley in 1999. The RCT conducted by Kirkley in 1999 showed different results than the RCT by Brouwer (2006), thus we decided to display the results from both studies in the present document (section 1a and 1b).

For part 1a, we found the results reported in the SR are not the same as the ones in the Brouwer 2006 RCT so we contacted the authors. The authors mentioned that the RCT reported results stemming from an analysis which forwarded last measurements available for subjects who were lost to follow-up or for whom data were incomplete. Results in the RCT were also adjusted for baseline characteristics which were not similar. The authors recommended that we report the data from the RCT.

Intervention description: The conservative treatment was identical in both groups and consisted of standard care: i.e., patient education (adaptation of activities and/or weight loss), and (if needed) physical therapy and analgesics. In the intervention group patients were fitted with a knee brace (OAsys brace, Innovation Sports, Irvine, CA, USA); this brace is commercially available for right/left leg in four sizes. The brace consists of a thigh shell and a calf shell (both of carbon fiber) connected by titanium hinges on the medial and lateral sides. The adjustable slide bar on the medial side of the brace provides

valgisation (1 to 12.5 degrees) with medial unloading, or varisation (1 to 10 degrees) with lateral unloading. The degree of varisation or valgisation depends on the degree of malalignment and the acceptance of the patient (extensive correction will cause pressure ulcers). A specialized orthopedic technician applied the brace and gave instructions to the patients. During the follow-up this specialized orthopedic technician was present at the orthopedic outpatient department. If necessary, the brace was adjusted during the follow-up visits.

Step 2: GRADE Summary of findings

Brace and standard conservative treatment compared to standard conservative treatment only for knee OA

Patient or population: patients with knee OA
Intervention: brace and standard conservative treatment
Comparison: standard conservative treatment only

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk	Corresponding risk					
	standard conservative treatment only	**Brace and standard conservative treatment**					
Benefits							
Pain VAS. Scale from: 0 to 10. Follow-up: 6 months	38%	43% (36% to 50%)[2]	5%	1.13	117 (1 study) [1]	⊕⊕⊕O moderate [3,4]	Not statistically significant
Knee function Hospital for Special Surgery Score (HSS). Scale from: 0 to 100. Follow-up: 6 months	24%	28% (23% to 35%)[2]	4%	1.17	117 (1 study) [1]	⊕⊕⊕O moderate [3,4]	Not statistically significant
Harms							
Withdrawal from treatment due to adverse events number of patients who stopped the treatment due to adverse events Follow-up: 12 months	7%[5]	0%	-7%	8.56 (0.47 to 155.45)	117 (1 study) [1]	⊕⊕OO low [3,4,6]	Not statistically significant
Withdrawals from treatment number of patients who stopped the treatment after randomization Follow-up: 12 months	25%	42% (24% to 72%)[7]	17%	1.70 (0.98 to 2.92)	117 (1 study) [1]	⊕⊕OO low [3,4,6]	Not statistically significant
Adherence	Not reported						

[1] The SR by Brouwer (2008) reported one trial by the same authors (Brouwer, 2006).

[2] We calculated the SMD using the mean difference and confidence interval between groups with RevMan. The MD was adjusted by the authors for baseline values for age, gender, BMI, duration of complaints, severity of knee OA, pain severity, knee function, walking distance, medication and quality of life since these characteristics were not similar at baseline.
[3] The trial (Brouwer, 2006) did not blind the outcome assessors, the care providers nor the patients. Outcomes of interest were not similar at baseline.
[4] The authors of the meta-analysis conducted the present study, which may lead to a potential conflict of interest. The quality was not downgraded because of this.
[5] Adverse events include skin irritation (n=2) and bad fit (n=2).
[6] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[7] Patients stopped treatment mostly because of lack of effectiveness (n=15).

[1. a]
Visual Summary of Findings Table
Brace and standard conservative treatment compared to standard conservative treatment only for knee OA

Chance: Improving pain after 6 months		
NNT: n/a		**Not statistically significant**
😐	57 people out of 100 don't improve whether they use a brace or not.	
🙂	38 people out of 100 improve whether they use a brace or not.	
🙂	**5 more people** out of 100 improve with a brace.	
Chance: Withdrawals due to treatment after 12 months		
NNH: n/a		**Not statistically significant**
😐	93 people out of 100 did not leave the study due to adverse events whether they use a brace or not.	
☹	7 people out of 100 left the study due to adverse events whether they use a brace or not.	
☹	**No more** people out of 100 left the study when they used a brace.	
Chance: Withdrawals due to any reason after 12 months		
NNH: n/a		**Not statistically significant**
😐	58 people out of 100 did not leave the study whether they use a brace or not..	
☹	25 people out of 100 left the study whether they use a brace or not.	
☹	**17 more** people out of 100 left the study when they used a brace.	

Chance: Adherence
Adherence to using a brace was not reported.

Step 3: GRADE Evidence profile

See Table 7 a: Braces and medical (conservative) treatment versus medical (conservative) treatment

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	● We are unable to recommend for or against the use of a brace with a *valgus* directing force for patients with medial uni-compartmental OA of the knee. ● We are unable to recommend for or against the use of a brace with a *varus* directing force for patients with lateral uni-compartmental OA of the knee. ● We suggest patients with symptomatic OA of the knee use patellar taping for short term relief of pain and improvement in function.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, *knee bracing*) and weight reduction.
OARSI	In patients with knee OA and mild/moderate *varus* or *valgus* instability, a knee brace can reduce pain, improve stability and diminish the risk of falling.

Step 5: GRADE Recommendation

7.2 Braces with medical (conservative) treatment versus medical (conservative) treatment alone in knee OA

Are braces in addition to medical treatment effective in reducing pain and improving function in patients with varus gonarthrosis compared to medical treatment alone?

Step 1: Search Results
Since an RCT conducted by Kirkley in 1999 showed different results than the RCT by Brouwer (2006), we decided to display the results from both studies in the present document (section 1a and 1b). The results shown in the present table were computed using the data sent to our research team by Dr. Brouwer, who had recently received it from the Kirkley Research Group but did not have time to report it in his systematic review.

Intervention description: The treatment that was provided in the medical treatment group represents the standard medical management of patients who have osteoarthritis of the knee. These patients were given an educational pamphlet on osteoarthritis, which described the pathological characteristics of the disease, how the diagnosis is determined, methods of coping, and the medical treatments available; instructions to use plain acetaminophen on an as-needed basis for relief of pain; and instructions on a home program to maintain flexibility. The regimen did not include formal physiotherapy. Patients who were taking nonsteroidal anti-inflammatory drugs at the time of presentation were asked to continue taking these medications as they had previously. All patients were asked to keep a diary about any medication that they used during the course of the trial. The patients in the unloader brace group had the same medical treatment as the control group, but they also were fitted with a Generation II valgus-producing functional knee (unloader) brace (Generation II Orthotics, Richmond, British Columbia, Canada). The brace is custom-made and consists of a polyethylene thigh shell connected to a polyethylene calf shell through a polyaxial hinge on the medial side. The hinge was

altered with use of a calibrated apparatus to allow application of a 4-degree increase in valgus in the anteroposterior plane. The patients were instructed to wear the brace while they were awake for activities that had been troublesome to them in the past and to keep a diary about their use of the brace.

Step 2: GRADE Summary of findings

Brace and medical treatment compared to medical treatment for knee OA

Patient or population: patients with knee OA
Intervention: brace and medical treatment
Comparison: medical treatment

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **Medical treatment**	Corresponding risk **brace and medical treatment**					
Benefits							
Pain WOMAC pain. Scale from: 0 to 500. Follow-up: 6 months	29%	64% (45% to 80%)[1]	35%	2.21	74 (1 study)	⊕⊕⊕O moderate[2]	3 (2 to 6)
Function WOMAC function. Scale from: 0 to 1700. Follow-up: 6 months	29%	58% (39% to 75%)[1]	29%	2	74 (1 study)	⊕⊕⊕O moderate[2]	3 (2 to 8)
Harms							
Withdrawals number of patients who withdrew from the study after randomization Follow-up: 6 months	18%	0% (0% to 19%)	-18%	0.07 (0.00 to 1.10)[3]	81 (1 study)	⊕⊕⊕O moderate[2]	Not statistically significant
Safety	Not reported						
Adherence	Not reported						

[1] The results shown in the present table were computed using the data sent to our research team by Dr. Brouwer who had recently received it from the Kirkley Research Group but did not have time to report it in his systematic review.
[2] Blinding of patients and assessors as well as intention-to-treat analyses were not mentioned in this study.
[3] We calculated this relative risk using Rev Man 5. Reasons for withdrawals include: dissatisfaction with the group to which they had been randomized (n=5), inability to attend appointments (n=2), ill health (n=1) and a change in a scheduled date for an operation (n=1).

[1. b]
Visual Summary of Findings Table
Brace and medical treatment compared to medical treatment for knee OA

Chance: Improving pain after 6 months	
NNT: 3	
😐 36 people out of 100 don't improve whether they use a brace or not.	
🙂 29 people out of 100 improve whether they use a brace or not.	
🙂 **35 more people** out of 100 improve with a brace.	
Chance: Improving function after 6 months	
NNT: 3	
😐 42 people out of 100 don't improve whether they use a brace or not.	
🙂 29 people out of 100 improve whether they use a brace or not.	
🙂 **29 more people** out of 100 improve with a brace.	
Chance: Withdrawals after 6 months	
NNH: n/a	**Not statistically significant**
😐 82 people out of 100 did not leave the study whether they use a brace or not.	
☹ 18 people out of 100 left the study whether they use a brace or not.	
☹ **No more** people out of 100 left the study when they used a brace.	
Chance: Safety	
Safety of using a brace was not reported	
Chance: Adherence	
Adherence to using a brace was not reported.	

Step 3: GRADE Evidence profile
See Table 7 b: Braces with medical (conservative) treatment versus medical (conservative) treatment alone

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	● We are unable to recommend for or against the use of a brace with a *valgus* directing force for patients with medial uni-compartmental OA of the knee. ● We are unable to recommend for or against the use of a brace with a *varus* directing force for patients with lateral uni-compartmental OA of the knee. ● We suggest patients with symptomatic OA of the knee use patellar taping for short term relief of pain and improvement in function.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, *knee bracing*) and weight reduction.
OARSI	In patients with knee OA and mild/moderate *varus* or *valgus* instability, a knee brace can reduce pain, improve stability and diminish the risk of falling.

Step 5: GRADE Recommendation

7.3 Braces and medical treatment versus neoprene sleeve with medical treatment in knee OA

Are braces in addition to medical treatment effective in reducing pain and improving function in patients with varus gonarthrosis compared to a neoprene sleeve combined with medical treatment?

Step 1: Search Results

The most recent SR on braces for knee OA was the one by Brouwer, 2008 which reported one RCT for braces versus neoprene sleeve conducted by Kirkley (1999). The results shown in the present table were computed using the data sent to our research team by Dr. Brouwer who had recently received it from the Kirkley Research Group but did not have time to report it in his systematic review.

Intervention description: Patients in the neoprene-sleeve group were directed to use the neoprene sleeve while they were awake for activities that had been troublesome to them in the past. Patients in the unloader-brace group were fitted with a Generation II valgus-producing functional knee brace. The brace is custom-made and consists of a polyethylene calf shell through a polyaxial hinge on the medial side. The hinge was altered with use of a calibrated apparatus to allow application of a 4-degree increase in valgus in the anteroposterior plane. Patients were instructed to wear the brace in the same way as the other group. The length of the treatment program was not clearly stated in the article. However, given there was a 6-month follow-up assessment, we assumed participants received treatment for that length of time.

Step 2: GRADE Summary of findings

Brace and medical treatment compared to neoprene sleeve and medical treatment for knee OA

Patient or population: patients with knee OA
Intervention: brace and medical treatment
Comparison: neoprene sleeve and medical treatment

Outcomes	Illustrative comparative risks* (95% CI)		Absolute effect	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk	Corresponding risk					
	neoprene sleeve and medical treatment	**brace and medical treatment**					
Benefits							
Pain WOMAC pain. Scale from: 0 to 500. Follow-up: 6 months	30%	47% (30% to 65%)[1]	17%	1.57	77 (1 study)	⊕⊕OO low[2,3]	Not statistically significant
Function WOMAC function. Scale from: 0 to 1700. Follow-up: 6 months	31%	45% (28% to 62%)[1]	14%	1.45	77 (1 study)	⊕⊕OO low[2,3]	Not statistically significant
Harms							
Withdrawals number of patients who withdrew from the study after randomization Follow-up: 6 months	5%	0% (0% to 20%)	-5%	0.19 (0.01 to 3.75)[4]	79 (1 study)	⊕⊕OO low[2,3]	Not statistically significant
Safety				Not reported			
Adherence				Not reported			

[1] The results shown in the present table were computed using the data sent to our research team by Dr. Brouwer who had recently received it from the Kirkley Research Group but did not have time to report it to his systematic review.
[2] Blinding of patients and assessors as well as intention-to-treat analyses were not mentioned in this study.
[3] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[4] We calculated this relative risk using Rev Man 5. Reasons for withdrawals for the 7 withdrawals in the control group and the 2 from the neoprene sleeve group include: dissatisfaction with the group to which they had been randomized (n=5), inability to attend appointments (n=2), ill health (n=1) and a change in a scheduled date for an operation (n=1) in the three treatment groups (brace, medical treatment and neoprene sleeve).

Step 3: GRADE Evidence profile

See Table 7 c: Braces and medical treatment versus neoprene sleeve with medical treatment

[1. c]

Visual Summary of Findings Table

Brace and medical treatment compared to neoprene sleeve and medical treatment for knee OA

Chance: Improving pain after 6 months		
NNT: 3		**Not statistically significant**
😐	53 people out of 100 don't improve with either treatment	
🙂	30 people out of 100 improve with either treatment	
🙂	**17 more people** out of 100 improve with a brace and medical treatment	
Chance: Improving function after 6 months		
NNT: 3		**Not statistically significant**
😐	55 people out of 100 don't improve with either treatment	
🙂	31 people out of 100 improve with either treatment	
🙂	**14 more people** out of 100 improve with a brace and medical treatment.	
Chance: Withdrawals after 6 months		
NNH: n/a		**Not statistically significant**
😐	95 people out of 100 did not leave the study with either treatment	
☹	5 people out of 100 left the study with either treatment.	

No more people out of 100 left the study with a brace and medical treatment	
Chance: Safety	
Safety of using a brace and medical treatment was not reported	
Chance: Adherence	
Adherence to using a brace and medical treatment was not reported.	

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	● We are unable to recommend for or against the use of a brace with a *valgus* directing force for patients with medial uni-compartmental OA of the knee. ● We are unable to recommend for or against the use of a brace with a *varus* directing force for patients with lateral uni-compartmental OA of the knee. ● We suggest patients with symptomatic OA of the knee use patellar taping for short term relief of pain and improvement in function.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, *knee bracing*) and weight reduction.
OARSI	In patients with knee OA and mild/moderate *varus* or *valgus* instability, a knee brace can reduce pain, improve stability and diminish the risk of falling.

Step 5: GRADE Recommendation

8. TAPING

8.1 Medially-directed patellar taping versus no taping in knee OA

Is medially-directed patellar taping effective in reducing pain and improving function in patients with symptomatic knee OA compared to no taping?

Step 1: Search Results
We chose the most recent SR conducted by Warden 2008 which pooled results from 2 studies on patellar taping in OA patients (Hinman, 2003 and Hinman, 2003) for pain. However, only one of these trials (published in the British Medical Journal) reported function, safety, adherence and withdrawals.

Intervention description in the RCT by Hinman 2003 published in BMJ:
The trial comprised a three week intervention period and a three week follow up. Tape was applied by 12 trained physiotherapists at the university (n=4) and in private practice (n=8) around the metropolitan region. The tape was worn for three weeks and reapplied weekly. Skin was shaved before application. Therapeutic tape provided medial glide, medial tilt, and anteroposterior tilt to the patella. As inflamed soft tissue is aggravated by stretch, tape was also applied to unload either the infrapatellar fat pad or the pes anserinus (determined by clinical assessment to ascertain the most tender). Hypoallergenic undertape (Fixomull stretch; Beiersdorf, North Rhyde, NSW) was applied beneath the rigid tape (Leuko Sportstape Premium Plus; Beiersdorf) to prevent irritation of the skin. Control tape aimed to provide sensory input only. Hypoallergenic tape alone was laid over the same areas of skin as the therapeutic tape. Participants allocated to the no tape group received no intervention. All participants continued current treatments but were instructed to refrain from starting new ones.

Intervention description in the crossover study by Hinman 2003 published in Rheumatology:
Therapeutic tape was applied in a standardized manner by the same investigator, regardless of clinical presentation. Skin was shaved prior to tape application. Two pieces of rigid tape (Leuko Sportstape Premium Plus, Beiersdorf Australia Ltd) applied a medial patellar glide and corrected lateral and AP tilt. Two further pieces of tape applied distal to the patella unloaded the infrapatellar fat pad. Hypoallergenic undertape (Fixomull1 stretch, Beiersdorf Australia Ltd) was applied beneath the rigid tape to prevent skin irritation. For the neutral taping condition, hypoallergenic undertape was applied over the same areas of skin as therapeutic tape, but with no force applied to realign the patella or unload soft tissues. Participants rested for 5 min between test conditions to minimize carry-over effects of tape on cutaneous sensation. The length of time the tape was worn and the timing of the outcome assessment was not reported.

Step 2: GRADE Summary of findings

Medially-directed patellar taping compared to no taping for knee OA

Patient or population: patients with knee OA
Intervention: medially-directed patellar taping
Comparison: no taping

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **No taping**	Corresponding risk **Medially-directed patellar taping**					
Benefits							
Pain[1] VAS. Scale from: 0 to 100. Follow-up: 3 weeks[2]	40%	82% (72% to 90%)[3]	42%	2.05	94 (2 studies[4])	⊕⊕OO low[5,6]	3 (2 to 3)
Function WOMAC. Scale from: 0 to 68. Follow-up: 3 weeks	37%	52% (32% to 71%)[7]	15%	1.41	58 (1 study[8])	⊕⊕OO low[9,10]	Not statistically significant
Harms							
Minor skin irritations number of subjects presenting with minor skin irritations Follow-up: 6 weeks	0%	28%	28%	17 (1.03 to 281.5)	58 (1 study[11])	⊕⊕OO low[9,10]	6 (0 to 3333) *by estimating control risk at 1%
Withdrawals number of patients who withdrew after randomization Follow-up: 6 weeks	3%	0% (0% to 27%)	-3%	0.33 (0.01 to 7.86)	58 (1 study[12])	⊕⊕OO low[9,10]	Not statistically significant
Adherence number of participants who continued to wear the tape as prescribed Follow-up: 6 weeks	100%	100%	0%	1	58 (1 study[13])	⊕⊕⊕O moderate[10]	Not statistically significant

[1] Two studies were pooled by the authors who reported a SMD (Hinman, 2003 and Hinman, 2003).
[2] One study looks at the immediate effect of taping and the other one at 3 weeks.
[3] This effect size was reported in the SR by Warden.
[4] One study was a crossover study and the other was a controlled study.
[5] According to the trials, both studies did not blind subjects and therapists who administered the treatment. However, subjects were not aware of which taping technique was considered therapeutic. Furthermore, because one of the studies (published in Rheumatology) used a crossover (within subject) design, it did not ensure proper allocation concealment and comparability of group characteristics at baseline. The quality assessment reported in the SR by Warden is not consistent with the information given in the RCTs.
[6] There is a publication bias indicated by significant funnel plot asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[7] We calculated the SMD with the end of study data using RevMan.
[8] The SR did not report function. One study (Hinman, 2003 in BMJ) reported function at 3 weeks.
[9] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[10] There is a possibility of publication bias since the funnel plot showed asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.

[11] One study (Hinman, 2003 in BMJ) reported adverse effects. Another study by the same author (Hinman, 2003 in Rheumatology) reported an absence of adverse effects.
[12] One study (Hinman, 2003 in BMJ) reported withdrawals.
[13] One study (Hinman, 2003 in BMJ) reported adherence.

Step 3: GRADE Evidence profile
See table 8 a: Medially-directed patellar taping versus no taping in knee OA

[2 a.]
Visual Summary of Findings Table
Medially-directed patellar taping compared to no taping for knee OA

Chance: Improving pain after 3 weeks		
NNT: 3		
😐	18 people out of 100 don't improve whether they applied taping or not.	
🙂	40 people out of 100 improve whether they applied taping or not.	
🙂	**42 more people** out of 100 improve with taping.	
Chance: Improving function after 3 weeks		
NNT: n/a		**Not statistically significant**
😐	48 people out of 100 don't improve whether they applied taping or not.	
🙂	37 people out of 100 improve whether they applied taping or not.	
🙂	**15 more people** out of 100 improve with taping.	
Chance: Minor skin irritation after 6 weeks		
NNH: 6		😐	72 people out of 100 did not have minor skin irritation whether they applied taping or not	
☹	No one had a minor skin irritation whether they applied taping or not	
☹	**28 more** people out of 100 had minor skin irritation when they applied tape.	
Chance: Withdrawals after 6 weeks		

NNH: n/a		**Not statistically significant**
😐	100 people out of 100 stayed in the study whether they applied taping or not.	
☹	3 people out of 100 left the study whether they applied taping or not.	
☺	**3 fewer** people out of 100 left the study when they applied tape.	
Chance: Adherence after 6 weeks		
NNH: n/a		**Not statistically significant**
😐	0 people out of 100 did not adhere to the treatment whether they use applied taping or not.	
☹	100 people out of 100 adhered to the treatment whether they applied taping or not.	
☹	**There was no difference** in the number of people who adhered to the treatment.	

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	● We are unable to recommend for or against the use of a brace with a *valgus* directing force for patients with medial uni-compartmental OA of the knee. ● We are unable to recommend for or against the use of a brace with a *varus* directing force for patients with lateral uni-compartmental OA of the knee. ● We suggest patients with symptomatic OA of the knee use patellar taping for short term relief of pain and improvement in function.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, *knee bracing*) and weight reduction.
OARSI	In patients with knee OA and mild/moderate *varus* or *valgus* instability, a knee brace can reduce pain, improve stability and diminish the risk of falling.

Step 5: GRADE Recommendation

8.2 Medially-directed patellar taping versus sham taping in knee OA

Is medially-directed patellar taping effective in reducing pain and improving function in patients with symptomatic knee OA compared to sham taping?

Step 1: Search Results

We chose the most recent SR conducted by Warden 2008 which pooled results from 3 studies on patellar taping in OA patients (Cushnaghan, 1994, Hinman, 2003 and Hinman, 2003) for pain.

Intervention description in the RCT by Hinman 2003 published in BMJ:

The trial comprised a three week intervention period and a three week follow up. Tape was applied by 12 trained physiotherapists at the university (n=4) and in private practice (n=8) around the metropolitan region. The tape was worn for three weeks and reapplied weekly. Skin was shaved before application. Therapeutic tape provided medial glide, medial tilt, and anteroposterior tilt to the patella. As inflamed soft tissue is aggravated by stretch, tape was also applied to unload either the infrapatellar fat pad or the pes anserinus (determined by clinical assessment to ascertain the most tender). Hypoallergenic undertape (Fixomull stretch; Beiersdorf, North Rhyde, NSW) was applied beneath the rigid tape (Leuko Sportstape Premium Plus; Beiersdorf) to prevent irritation of the skin. Control tape aimed to provide sensory input only. Hypoallergenic tape alone was laid over the same areas of skin as the therapeutic tape. Participants allocated to the no tape

group received no intervention. All participants continued current treatments but were instructed to refrain from starting new ones.

Intervention description in the crossover study by Hinman 2003 published in Rheumatology:
Therapeutic tape was applied in a standardized manner by the same investigator, regardless of clinical presentation. Skin was shaved prior to tape application. Two pieces of rigid tape (Leuko Sportstape Premium Plus, Beiersdorf Australia Ltd) applied a medial patellar glide and corrected lateral and AP tilt. Two further pieces of tape applied distal to the patella unloaded the infrapatellar fat pad. Hypoallergenic undertape (Fixomull1 stretch, Beiersdorf Australia Ltd) was applied beneath the rigid tape to prevent skin irritation. For the neutral taping condition, hypoallergenic undertape was applied over the same areas of skin as therapeutic tape, but with no force applied to realign the patella or unload soft tissues. Participants rested for 5 min between test conditions to minimize carry-over effects of tape on cutaneous sensation. The length of time the tape was worn and the timing of the outcome assessment was not reported.

Intervention description of the crossover study by Cushnaghan, 1994 : The three types of taping were: neutral, in which the tape was applied directly over the front of the patella, without any pressure; medial, in which the tape pulled the patella to the medial side of the knee joint; and lateral, in which the tape was used to pull the patella to the lateral side. The taping consisted of a strip of Leukotape P (Beiersdorf, UK) applied by the same person in each case. Each tape was applied for four days, with three days of no treatment between tape positions.

Step 2: GRADE Summary of findings

Medially-directed patellar taping compared to sham taping for knee OA

Patient or population: patients with knee OA
Intervention: medially-directed patellar taping
Comparison: sham taping

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **sham taping**	Corresponding risk **medially-directed patellar taping**					
Benefits							
Pain[1] VAS. Scale from: 0 to 100. Follow-up: 3 weeks[2]	41%	68% (52% to 81%)[3]	27%	1.66	122 (3 studies[4])	⊕⊕OO low [5,6]	4 (3 to 8)
Function WOMAC. Scale from: 0 to	38%	37% (19% to 57%)	-1%	0.97	58 (1 study[7])	⊕⊕OO low [8, 9]	Not statistically significant

68. Follow-up: 3 weeks							
Harms							
Minor skin irritations number of subjects presenting with minor skin irritations Follow-up: 3 weeks	3%	27% (4% to 100%)	24%	8 (1.07 to 59.95)	58 (1 study[10])	⊕⊕OO low [8,9]	36 (1 to 476)
Adherence number of participants who continued to wear the tape as prescribed Follow-up: 6 weeks	100%	100%	0%	1	58 (1 study[11])	⊕⊕⊕O moderate [9]	Not statistically significant
Withdrawals number of participants who withdrew after randomization Follow-up: 6 weeks	0%	0%	0%	1	58 (1 study[11])	⊕⊕⊕O moderate [9]	Not statistically significant

[1] Three studies were pooled by the systematic review authors who reported a SMD (Hinman, 2003, Hinman, 2003 and Cushnagan, 1994).
[2] Studies looked at the immediate effect of taping as well as the effect after 4 days and after 3 weeks of intervention.
[3] This effect size was reported in the SR by Warden.
[4] Two were crossover studies and one was an RCT.
[5] According to the trials, all studies did not blind subjects and therapists who administered the treatment. However, subjects were not aware of which taping technique was considered therapeutic. Furthermore, because the two other studies used a crossover (within subject) design, it did not ensure proper allocation concealment and comparability of group characteristics at baseline. The quality assessment reported in the SR by Warden is not consistent with the information given in the RCTs.
[6] There is a publication bias indicated by significant funnel plot asymmetry. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[7] The SR did not report function. One study (Hinman, 2003 in BMJ) reported function at 3 weeks.
investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[8] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[9] There is a possibility of publication bias since the funnel plot showed asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[10] One study (Hinman, 2003 in BMJ) reported adverse effects. The other studies reported an absence of adverse effects.
[11] One study (Hinman, 2003 in BMJ) reported adherence to the treatment regimen and withdrawals. Cushnagan also reported that all patients followed prescribe taping.

[2 b.]

Visual Summary of Findings Table
Medially-directed patellar taping compared to sham taping for knee OA

Chance: Improving pain after 3 weeks	
NNT: 4	
😐 32 people out of 100 don't improve no matter which type of taping was used.	
🙂 41 people out of 100 improve no matter which type of taping was used.	
🙂 **27 more people** out of 100 improve with medially-directed patellar taping.	
Chance: Improving function after 3 weeks	
NNT: n/a	**Not statistically significant**
😐 63 people out of 100 don't improve no matter which type of taping was used.	
🙂 37 people out of 100 improve no matter which type of taping was used.	
☹ **1 fewer person** out of 100 improve with medially-directed patellar taping.	
Chance: Minor skin irritation after 3 weeks	
NNH: 36	
😐 73 people out of 100 did not have minor skin irritation with either type of taping.	
☹ 3 people out of 100 had minor skin irritation with either type of taping.	
☹ **24 more** people out of 100 had minor skin irritation with medially-directed patellar taping.	
Chance: Adherence after 6 weeks	
NNH: n/a	**Not statistically significant**
😐 100 people out of 100 adhered to the treatment with either type of taping.	
☹ No one did not adhere to the treatment with either type of taping.	

☹	**There was no difference in the number of people** who adhered to either type of taping.	
Chance: Withdrawals		
NNH: n/a		**Not statistically significant**
😐	100 people out of 100 remained in the study with either type of taping.	
☹	No one left the study with either type of taping	
☹	**There was no difference** in the number of people who left the study with either type of taping.	

Step 3: GRADE Evidence profile

Table 8 b: Medially-directed patellar taping versus sham taping in knee OA

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	● We are unable to recommend for or against the use of a brace with a *valgus* directing force for patients with medial uni-compartmental OA of the knee. ● We are unable to recommend for or against the use of a brace with a *varus* directing force for patients with lateral uni-compartmental OA of the knee. ● We suggest patients with symptomatic OA of the knee use patellar taping for short term relief of pain and improvement in function.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, *knee bracing*) and weight reduction.
OARSI	In patients with knee OA and mild/moderate *varus* or *valgus* instability, a knee brace can reduce pain, improve stability and diminish the risk of falling.

Step 5: GRADE Recommendation

8.3 Laterally-directed patellar taping versus medially-directed patellar taping in knee OA

Is laterally-directed patellar taping effective in reducing pain and improving function in patients with symptomatic knee OA compared to medially-directed patellar taping?

Step 1: Search Results

We chose the most recent SR conducted by Warden 2008 which reported one study comparing lateral to medial patellar taping in OA patients for pain (Cushnaghan, 1994).

Intervention description: The three types of taping in the Cushnaghan study were: neutral, in which the tape was applied directly over the front of the patella, without any pressure; medial, in which the tape pulled the patella to the medial side of the knee joint; and lateral, in which the tape was used to pull the patella to the lateral side. The taping consisted of a strip of Leukotape P (Beiersdorf, UK) applied by the same person in each case. Each tape was applied for four days, with three days of no treatment between tape positions.

Step 2: GRADE Summary of findings

Laterally-directed patellar taping compared to medially-directed patellar taping for knee OA

Patient or population: patients with knee OA
Intervention: laterally-directed patellar taping
Comparison: medially-directed patellar taping

Outcomes	Illustrative comparative risks* (95% CI)		Absolute difference	Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	NNT
	Assumed risk **medially-directed patellar taping**	Corresponding risk **laterally-directed patellar taping**					
Benefits							
Pain VAS. Scale from: 0 to 100. Follow-up: 4 days		*Not estimable due to lack of data	SMD 0.95 (0.42 to 1.48) [1]	*	28 (1 study[2])	⊕⊕◯◯ low [3,4]	*
Function	Not reported						
Harms							
Safety number of patients who reported adverse events follow-up: 4 days	0%	0%	0%	1	28 (1 study[2])	⊕⊕◯◯ low [3,4]	Not statistically significant
Adherence number of patients who wore tapes on for the full four days follow-up: 4 days	100%	100%	0%	1	28 (1 study[2])	⊕⊕◯◯ low [3,4]	Not statistically significant
Withdrawals number of patients who withdrew after entry to the study follow-up: 4 days	0%	0%	0%	1	28 (1 study[2])	⊕⊕◯◯ low [3,4]	Not statistically significant

[1] The SR by Warden reported an SMD for pain comparing lateral and medial taping based on the Cushnagan, 1994 study.
[2] This study has a crossover design with 14 participants.
[3] This study did not blind therapists who administered the treatment and it is unclear if patients were blinded. However, subjects were not aware of which taping technique was considered therapeutic. Also, because this study used a crossover (within subject) design, it did not ensure proper allocation concealment and comparability of group characteristics at baseline.
[4] There is a possibility of publication bias since the funnel plot showed asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.

[2 c.]
Visual Summary of Findings Table
Laterally-directed patellar taping compared to medially-directed patellar taping for knee OA

Chance: Improving pain after 4 days		
The improvement in pain was not estimable due to lack of data.		
Chance: Improving function after 4 days		
The improvement in function was not reported.		
Chance: Safety		
NNH: n/a		**Not statistically significant**
😐	100 people out of 100 did not have adverse events with either type of taping	
☹	No one had adverse events with either type of taping	
☹	**There was no difference** in the safety of the two types of taping.	
Chance: Adherence after 4 days		
NNH: n/a		**Not statistically significant**
😐	100 people out of 100 adhered to either type of taping	
☹	No one did not adhere to the treatment with either type of taping	
☹	**There was no difference** in the number of people who adhered to either type of taping**.**	
Chance: Withdrawals after 4 days		
NNH: n/a		**Not statistically significant**
😐	100 people out of 100 remained in the study with either type of taping.	
☹	No one left the study with either type of taping	
☹	**There was no difference** in the number of people who left the study with either type of taping.	

Step 3: GRADE Evidence profile
See Table 8c: Laterally-directed patellar taping versus medially-directed patellar taping in knee OA

Step 4: Other recommendations

Group	Recommendation
AAOS (knee)	● We are unable to recommend for or against the use of a brace with a *valgus* directing force for patients with medial uni-compartmental OA of the knee. ● We are unable to recommend for or against the use of a brace with a *varus* directing force for patients with lateral uni-compartmental OA of the knee. ● We suggest patients with symptomatic OA of the knee use patellar taping for short term relief of pain and improvement in function.
EULAR	Non-pharmacological treatment of knee OA should include education, exercise, appliances (sticks, insoles, *knee bracing*) and weight reduction.
OARSI	In patients with knee OA and mild/moderate *varus* or *valgus* instability, a knee brace can reduce pain, improve stability and diminish the risk of falling.

Step 5: GRADE Recommendation

Table 1 a: Home-based balance exercises versus home-based strengthening exercises for knee OA

Author(s): Karine Toupin April
Date: 2009-06-12
Question: Should balance training versus strength training be used for knee OA?
Bibliography: Chaipinyo, 2009

Quality assessment							Summary of findings					
							No of patients		Effect			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	balance training	strength training	Relative (95% CI)	Absolute	Quality	Importance
pain (follow-up 4 weeks; measured with: Knee injury and Osteoarthritis Outcome Score (KOOS); range of scores: 0-100; Better indicated by higher values)												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness[2]	serious[3]	None	24	18	0.73	SMD -0.23 (-0.85 to 0.38)[4]	⊕⊕OO LOW	CRITICAL
function in daily living (follow-up 4 weeks; measured with: Knee injury and Osteoarthritis Outcome Score (KOOS); range of scores: 0-100; Better indicated by higher values)												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness[2]	serious[3]	None	24	18	0.54	SMD -0.45 (-1.07 to 0.17)[4]	⊕⊕OO LOW	CRITICAL
Adherence (follow-up 4 weeks; Maximum number of days:28; measured with: average number of days of exercise performed by participants Better indicated by higher values)												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness[2]	serious[3]	None	24	18	-	MD 2 (-0.77 to 4.77)	⊕⊕OO LOW	CRITICAL
Withdrawals												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness[2]	serious[3]	None	0/24 0%	6/24 (25%)	0.08 (0.00 to 1.29)	23 fewer per 100 (from 25 fewer to 7 more)[5]	⊕⊕OO LOW	CRITICAL
Safety												
Not reported												

[1] The physiotherapists prescribing the exercises were not blinded to group allocation. We did not downgrade the quality assessment score for this. However, the number of patients in this trial is small (n=42), which could undermine its validity.
[2] Participants were volunteers from the community 50 years and older. We did not downgrade the quality assessment score for this.
[3] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[4] The authors report the mean difference over time between groups but it does not coincide with our results using Rev Man 5 because the authors did not report the level of accuracy needed (no decimals reported). We calculated the SMD using Rev Man 5.
[5] Withdrawals were due to other illnesses, personal reasons or impossibility to reach patients.

Table 1 b: Balance exercises in addition to strengthening exercises versus strengthening exercises alone for knee OA

Author(s): Karine Toupin April
Date: 2009-06-12
Question: Should kinesthesia and balance exercises in addition to strengthening exercises versus strengthening exercises be used for knee OA?
Bibliography: Diracoglu, 2005

Quality assessment							Summary of findings					
							No of patients		Effect			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	kinesthesia and balance exercises in addition to strength exercises	strength exercises	Relative (95% CI)	Absolute	Quality	Importance
physical function (follow-up 8 weeks; measured with: WOMAC; range of scores: 0-10; Better indicated by lower values)												
1	randomised trials	serious[1]	No serious inconsistency	no serious indirectness[2]	Serious[3]	None	30	30	1.55	SMD 0.46 lower (0.97 lower to 0.05 higher)[4]	⊕⊕OO LOW	CRITICAL
Pain												
No evidence available[5]												
Adverse effects (follow-up 8 weeks; number of patients with event)												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness[2]	no serious imprecision	none	0/30 (0%)	0/30 (0%)	1	0 more per 100	⊕⊕⊕O MODERATE	CRITICAL
Adherence (follow-up 8 weeks; Maximum number of visits:24; mean number of missed visits)												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness	no serious imprecision	none	24	24	-	MD -2	⊕⊕⊕O MODERATE	CRITICAL
Withdrawals (follow-up 8 weeks; number of patients who withdrew after randomization)												
1	randomised trials	serious[1]	no serious inconsistency	no serious indirectness	no serious imprecision	none	3/33 (9.1%)	3/33 (9.1%)	1 (0.22 to 4.6)	0 fewer per 100 (from 7 fewer to 33 more)[6]	⊕⊕⊕O MODERATE	CRITICAL

[1] The randomization method used is the "one-to-one" method which allocates one patient to the study group and the other patient to the control group one by one according to their order of application to the outpatient clinic. This method could lead to biases. Furthermore, blinding was not reported and intention to treat analyses were not performed.
[2] All patients included in the study were women 35 to 65 years old. We did not downgrade the quality of the study because of this.
[3] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[4] The authors reported the end of study results in both groups, which showed a statistically significant difference. However, their results did not coincide with our results from Rev Man 5 because the authors did not report the level of accuracy needed.
[5] Pain was not measured in the RCT. However, the use of paracetamol was reported, which could represent a proxy measure for pain to some extent. The authors report that 5 patients used paracetamol during the study in a dosage of less than 500 mg daily. The 2 groups were not significantly different from each other regarding paracetamol use (P > 0.05).
[6] Patients withdrew because of the difficulty to come to the clinic for exercises.

Table 2 a: Laterally wedged insoles versus neutrally wedged insoles for knee OA

Author(s): Jessie McGowan, Maria Benkhalti, Karine Toupin April
Date: 2009-04-28
Question: Should Laterally wedged insoles versus neutrally wedged insoles be used for painful medial Knee OA?
Bibliography: Brouwer, 2008

Quality assessment							Summary of findings					Importance
							No of patients		Effect		Quality	
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Laterally wedged insoles	neutrally wedged insoles	Relative (95% CI)	Absolute		
Pain (follow-up 6 months; measured with: WOMAC; range of scores: 0-100; Better indicated by less)												
1	randomised trial	serious[1]	No serious inconsistency	no serious indirectness	Serious[2]	None	78	69	0.71	SMD 0.31 (-0.01 to 0.64)[3]	⊕⊕OO LOW	CRITICAL
Physical function (follow-up mean 6 months; measured with: WOMAC; range of scores: 0-100; Better indicated by less)												
1	randomised trial	serious[1]	No serious inconsistency	no serious indirectness	Serious[2]	None	78	69	0.71	SMD 0.30 (-0.03 to 0.62)[4]	⊕⊕OO LOW	CRITICAL
Adherence (follow-up 6 months; number of patients who wore insoles permanently during the study period)												
1	randomised trial	serious[1]	No serious inconsistency	no serious indirectness	no serious imprecision	None	72/82 (87.8%)	55/74 (74.3%)	1.18 (1.01 to 1.38)	13 more per 100 (from 1 more to 28 more)	⊕⊕⊕O MODERATE	CRITICAL
Withdrawals due to intolerance to the treatment (follow-up 6 months; number of patients who withdrew from the study because of intolerance to the treatment)												
1	Randomized trial	serious[1]	No serious inconsistency	no serious indirectness	Serious[2]	None	0/82 (0%)	1/74 (1.4%)	0.30 (0.01 to 7.28)	1 more per 100 (from 1 more to 8 more)	⊕⊕OO LOW	CRITICAL

[1] The randomization procedure and allocation concealment were not described. The trial (Maillefert, 2001) did not blind the outcome assessors and the care providers. The insoles were individually modeled and therefore the intervention was not identical for all patients. The quality assessment score was not reduced because of this.
[2] The confidence interval ranges from not being clinically significant to a very large clinical effect, which shows imprecision.
[3] This SMD was calculated using RevMan 5 with the 6-month end of study data. WOMAC pain was more decreased in the neutrally wedged group than the laterally wedged group. This result along with those at 1, 3, 12 and 24 months is not statistically significant.
[4] This SMD was calculated using RevMan 5 with the 6-month end of study data. WOMAC function was more decreased in the laterally wedged group than the neutrally wedged group. This result along with those at 1, 3, 12 and 24 months is not statistically significant.

Table 2 b: Medial wedged insoles versus neutrally wedged insoles for knee OA

Author(s): Karine Toupin April
Date: 2009-05-01
Question: Should Medially wedged insoles versus neutrally wedged insoles be used for knee OA?
Bibliography: Rodrigues 2008

Adherence												
Not reported												

[1] The randomization procedure was done according to birth date and the allocation concealment was not described. The trials (Toda, 2001, 2004 and 2006) did not blind the outcome assessors, the care providers or the patients.
[2] This SMD was calculated using Rev Man 5 with the 6-months end of study data. This result along with the one at 8 weeks are statistically significant (SMD= -0.42 (-0.83, 0)). The data at 24 month were not statistically significant.
[3] This SMD was calculated using Rev Man 5 with the 6-months end of study data. This result along with the one at 8 weeks and 24 months are not statistically significant.
[4] The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.

[5] In the strapped insole group, 3 participants complained of popliteal pain, 2 reported low back pain and one had foot sole pain. Only one patient complained of foot sole pain in the inserted insole group. However, side effects were not severe enough to deter participants from continuing to wear the insole.
[6] People who withdrew had either moved or cited household commitments.

Adverse effects (number of patients who discontinued the treatment programs because of increase of complaints)												
1	randomised trials	no serious limitations[1]	no serious inconsistency	no serious indirectness	serious[2]	None	3/56 (5.4%)	2/53 (3.8%)	1.42 (0.25 to 8.16)	2 more per 100 (from 3 fewer to 27 more)[5]	⊕⊕⊕O MODERATE	CRITICAL
Losses to follow-up (follow-up 29 weeks; number of patients who were lost to follow-up)												
1	randomised trials	no serious limitations[1]	no serious inconsistency	no serious indirectness	serious[2]	None	12/56 (21.4%)	9/53 (17%)	1.26 (0.58 to 2.75)	4 more per 100 (from 7 fewer to 30 more)[5]	⊕⊕⊕O MODERATE	CRITICAL

[1] This trial was a single-blind study. The authors mention that it was not possible to blind either patients or therapists for the allocated treatment. Therefore, extra attention was given to the blinding of the outcome assessor. A placebo effect may also be present in this study due to the nature of the interventions. Finally, a limitation of the study is the relatively large number of patients who received total hip arthroplasty during the follow-up period. However, no significant differences were found between the conclusions based on the intention-to-treat analysis and the per-protocol analysis. The quality of the study was not downgraded because of these reasons.

[2] The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.
[3] This SMD was calculated with RevMan 5 with the end-of-study data at the end of the treatment period (5-weeks).
[4] This SMD was calculated with RevMan 5 with the end-of-study data at 29 weeks of follow-up.
[5] In the exercise program, one patient also discontinued treatment because of cardio-respiratory disease.

Table 4 b: Manual therapy in combination with supervised exercise and home exercise program versus home exercise program alone for knee OA

Author(s): Karine Toupin April
Date: 2009-08-19
Question: Should manual therapy in combination with supervised exercise and home exercise program vs home exercise be used for knee OA?
Bibliography: Deyle, 2005

Quality assessment							Summary of findings					
							No of patients		Effect			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Manual therapy+ supervised exercise and home exercise program	Home exercise	Relative (95% CI)	Absolute	Quality	Importance
pain (follow-up 8 weeks; measured with: WOMAC; range of scores: 0-500; Better indicated by lower values)												
1[1]	randomised trials	no serious limitations[2]	no serious inconsistency	no serious indirectness	no serious imprecision	none	60	60	1.43	SMD -0.41 (-0.77 to -0.05)	⊕⊕⊕⊕ HIGH	CRITICAL
function (follow-up 8 weeks; measured with: WOMAC; range of scores: 0-1700; Better indicated by lower values)												
1	randomised trials	no serious limitations	no serious inconsistency	no serious indirectness	no serious imprecision	none	60	60	1.41	SMD -0.40 (-0.76 to -0.03)	⊕⊕⊕⊕ HIGH	CRITICAL
Discontinuations due to lack of adherence (follow-up 8 weeks; number of patients who were discontinued to lack of adherence to the treatment regimen)												
1	randomised trials	no serious limitations	no serious inconsistency	no serious indirectness	no serious imprecision	none	0/60 (0%)	0/60 (0%)	0 (0 to 0)	0 fewer per 100 (from 0 fewer to 0 fewer)	⊕⊕⊕⊕ HIGH	CRITICAL
Withdrawals (follow-up 8 weeks; people who withdrew from the study after randomization)												
1	randomised trials	no serious limitations	no serious inconsistency	no serious indirectness	serious[3]	none	6/66 (9.1%)[4]	8/68 (11.8%)[5]	RR 0.77 (0.28 to 2.11)	3 fewer per 100 (from 8 fewer to 13 more)	⊕⊕⊕O MODERATE	CRITICAL

[1] Another outcome reported by the author was the use of medications for OA by patients at 52 weeks. Use of medications for OA was higher in the home exercise group (68%) than the clinic treatment group (48%) and this difference was statistically significant (p=0.03).
[2] The authors report that the intention to treat results with 134 subjects did not differ substantially from the results of the 120 subjects.
[3] The confidence interval ranges from not being clinically significant to a very large clinical effect, which is a sign of imprecision.
[4] In the treatment group, withdrawals were due to: knee injections (2), changed medications (1), not willing to return (1), not willing to walk (1) and unrelated medical condition (1).
[5] In the control group, withdrawals were due to: knee injections (1), changed medications (1), shoulder surgery (1), not willing to return (2) and moved from area (3).

[1] The trial (Brouwer, 2006) did not blind the outcome assessors, the care providers nor the patients. Outcomes of interest were not similar at baseline.
[2] The authors of the meta-analysis conducted the present study, which may lead to a potential conflict of interest. The quality was not downgraded because of this.
[3] We calculated the SMD using the mean difference and confidence interval between groups with RevMan. The MD was adjusted by the authors for baseline values for age, gender, BMI, duration of complaints, severity of knee OA, pain severity, knee function, walking distance, medication and quality of life since these characteristics were not similar at baseline.
[4] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[5] Adverse events include skin irritation (n=2) and bad fit (n=2).
[6] Patients stopped treatment mostly because of lack of effectiveness (n=15).

Table 7 b: Braces and medical (conservative) treatment versus medical (conservative) treatment alone in knee OA

[1] One study looks at the immediate effect of taping and the other one at 3 weeks.
[2] One study was a crossover study and the other was a controlled study.
[3] According to the trials, both studies did not blind subjects and therapists who administered the treatment. However, subjects were not aware of which taping technique was considered therapeutic. Furthermore, because one of the studies (published in Rheumatology) used a crossover (within subject) design, it did not ensure proper allocation concealment and comparability of group characteristics at baseline. The quality assessment reported in the SR by Warden is not consistent with the information given in the RCTs.
[4] There is a publication bias indicated by significant funnel plot asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[5] The study in BMJ included 29 in each group and the crossover study in Rheumatology included 18 patients who had both medially-directed taping and no taping.
[6] This effect size was reported in the SR by Warden.
[7] The SR did not report function. One study (Hinman, 2003 in BMJ) reported function at 3 weeks.
[8] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[9] There is a possibility of publication bias since the funnel plot showed asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[10] We calculated the SMD with the end of study data using RevMan.
[11] One study (Hinman, 2003 in BMJ) reported adverse effects. Another study by the same author (Hinman, 2003 in Rheumatology) reported an absence of adverse effects.

[12] One study (Hinman, 2003 in BMJ) reported withdrawals.
[13] One study (Hinman, 2003 in BMJ) reported adherence.

Withdrawals												
1[11]	randomised trials	no serious limitations	no serious inconsistency	no serious indirectness	no serious imprecision	Reporting bias[9]	0/29 (0%)	0/29 (0%)	1	0 fewer per 100 (from 100 fewer to 100 fewer)	⊕⊕⊕O MODERATE	CRITICAL

[1] Studies looked at the immediate effect of taping as well as the effect after 4 days and after 3 weeks of intervention.
[2] Two were crossover studies and one was an RCT.
[3] According to the trials, studies did not blind subjects (though it is unclear in the Cushnagan study if patients were blinded) and therapists who administered the treatment. However, subjects were not aware of which taping technique was considered therapeutic. Furthermore, because the two other studies used a crossover (within subject) design, it did not ensure proper allocation concealment and comparability of group characteristics at baseline. The quality assessment reported in the SR by Warden is not consistent with the information given in the RCTs.
[4] There is a publication bias indicated by significant funnel plot asymmetry. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[5] The study published by Hinman in BMJ included 29 in each group, the study by the same author in Rheumatology included 18 patients and the study by Cushnagan included 14 patients.

[6] This effect size was reported in the SR by Warden.
[7] The SR did not report function. One study (Hinman, 2003 in BMJ) reported function at 3 weeks.
[8] The confidence interval ranges from not being clinically significant to a large clinical effect, which shows imprecision.
[9] There is a possibility of publication bias since the funnel plot showed asymmetry in the SR. This asymmetry indicates that negative studies investigating patellar taping are less likely to be published and smaller studies are more likely to produce larger effect sizes.
[10] One study (Hinman, 2003 in BMJ) reported adverse effects. The other studies reported an absence of adverse effects.
[11] One study (Hinman, 2003 in BMJ) reported adherence to the treatment regimen. Cushnagan also reported that all patients followed prescribe taping.

2022 American College of Rheumatology/American Association of Hip and Knee Surgeons Guideline for the Perioperative Management of Antirheumatic Medication in Patients With Rheumatic Diseases Undergoing Elective Total Hip or Total Knee Arthroplasty

Susan M. Goodman,[1] Bryan D. Springer,[2] Antonia F. Chen,[3] Marshall Davis,[4] David R. Fernandez,[1] Mark Figgie,[1] Heather Finlayson,[5] Michael D. George,[6] Jon T. Giles,[7] Jeremy Gilliland,[8] Brian Klatt,[9] Ronald MacKenzie,[1] Kaleb Michaud,[10] Andy Miller,[1] Linda Russell,[1] Alexander Sah,[11] Matthew P. Abdel,[12] Beverly Johnson,[13] Lisa A. Mandl,[1] Peter Sculco,[1] Marat Turgunbaev,[14] Amy S. Turner,[14] Adolph Yates Jr.,[9] and Jasvinder A. Singh[15]

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the physician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions, and drug formularies or other third-party analyses that cite ACR guidelines should state this. These recommendations cannot adequately convey all uncertainties and nuances of patient care. The ACR is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

Objective. To develop updated guidelines for the perioperative management of disease-modifying medications for patients with rheumatic diseases, specifically those with inflammatory arthritis (IA) and those with systemic lupus erythematosus (SLE), undergoing elective total hip arthroplasty (THA) or elective total knee arthroplasty (TKA).

Methods. We convened a panel of rheumatologists, orthopedic surgeons, and infectious disease specialists, updated the systematic literature review, and included currently available medications for the clinically relevant population, intervention, comparator, and outcomes (PICO) questions. We used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology to rate the quality of evidence and the strength of recommendations using a group consensus process.

Results. This guideline updates the 2017 recommendations for perioperative use of disease-modifying antirheumatic therapy, including traditional disease-modifying antirheumatic drugs, biologic agents, targeted synthetic small-molecule drugs, and glucocorticoids used for adults with rheumatic diseases, specifically for the treatment of patients with IA, including rheumatoid arthritis and spondyloarthritis, those with juvenile idiopathic arthritis, or those with SLE who are undergoing elective THA or TKA. It updates recommendations regarding when to continue, when to withhold, and when to restart these medications and the optimal perioperative dosing of glucocorticoids.

Conclusion. This updated guideline includes recently introduced immunosuppressive medications to help decision-making by clinicians and patients regarding perioperative disease-modifying medication management for patients with IA and SLE at the time of elective THA or TKA.

INTRODUCTION

Advances in antirheumatic therapy have led to remarkable improvements in treatment and quality of life for people with rheumatic musculoskeletal diseases (RMDs); however, total hip arthroplasty (THA) and total knee arthroplasty (TKA) remain a mainstay of treatment among RMD patients with advanced symptomatic joint damage, most frequently those with inflammatory arthritis (IA), including spondylarthritis (SpA), rheumatoid arthritis (RA), or psoriatic arthritis (PsA), and those with systemic lupus erythematosus (SLE) (1–7). THA and TKA are successful procedures that improve mobility and decrease pain for people with RMD and end-stage arthritis. However, the risk of superficial and deep periprosthetic joint infection (PJI), a devastating complication, is increased after surgery in people with RMD, and avoiding infection is a top priority for them: patients with RA have a 50% increased risk of PJI compared to those with osteoarthritis (8,9). A panel of patients with RA was convened in 2017 prior to the publication of the American College of Rheumatology/American Association of Hip and Knee Surgeons (ACR/AAHKS) perioperative guideline and clearly stated that any risk of infection, while rare, was much more significant to them than the possibility of a postoperative flare, despite flares reported in >60% of patients after surgery (8,10–12). Recommendations regarding perioperative management of antirheumatic medications in the 2017 ACR/AAHKS guideline need updating to include drugs introduced in the interim, as well as review of more recent relevant publications.

The optimal strategy for perioperative medication management remains unknown, but antirheumatic therapy is a readily modifiable risk factor for infection, whereas other risk factors for adverse outcomes, including disease activity or severity or long-term glucocorticoid (GC) use, may not be modifiable (13–15). The ACR systematically updates guidelines every 5 years; therefore, to update the 2017 perioperative medication management guideline, the ACR and AAHKS convened a panel of rheumatologists, orthopedic surgeons, and infectious disease specialists and conducted a systematic review of the new literature published since the last guideline, adding new medications to those previously available, although direct applicable evidence remains sparse in the literature. This guideline applies to management of antirheumatic medication for adult patients with IA, including those with RA, SpA, PsA, or ankylosing spondylitis (AS), adults with juvenile idiopathic arthritis (JIA), and adult patients with SLE undergoing elective THA or TKA.

Given the increased infection risk seen in patients with IA and patients with SLE undergoing these procedures, the existing evidence base used to guide our recommendations, the time afforded by these elective procedures to manage medications, and the frequent use of these procedures in patients with IA or SLE (4,6,16), we have restricted our recommendations to those undergoing either THA or TKA. A guideline cannot address all clinical situations and scenarios but seeks to provide recommendations for commonly encountered clinical problems.

While the principles surrounding these recommendations may be extrapolated and applied to other surgical procedures, it should be noted that the evidence and consensus used to inform this guideline were drawn primarily from orthopedic literature. As in the prior version, this guideline does not address indications for THA or TKA, medical decisions unrelated to antirheumatic drug therapy, the choice of the implant, the surgical approach, or the perioperative evaluation and management of concurrent disease, such as that affecting the cervical spine of patients with RA. Although routine perioperative care and preoperative optimization for patients with RA, SpA, JIA, or SLE include assessing risk of venous thromboembolism and major acute coronary events (17,18), this guideline does not address cardiac risk assessment or perioperative venous thromboembolism prophylaxis, as both are covered in existing guidelines (19–22). The goal of this updated guideline is to provide optimal support for clinicians and patients making decisions regarding medication management at the time of elective THA or TKA surgery.

METHODS

This guideline was developed following the ACR guideline development process and in accordance with ACR policies guiding

Submitted for publication February 9, 2022; accepted in revised form April 7, 2022.

Table 1. Populations included in this guideline*

Adults age ≥18 years diagnosed with RA, SpA, including AS and PsA, JIA, or SLE who are deemed to be appropriate surgical candidates, are undergoing elective THA or TKA, and who are receiving antirheumatic drug therapy at the time of surgery
All patients carrying the above diagnoses without restriction to those meeting classification criteria
SLE includes patients with severe or not severe SLE, defined as follows
Severe SLE: currently treated (induction or maintenance) for severe organ manifestations: lupus nephritis, CNS lupus, severe hemolytic anemia (hemoglobin <9.9 gm/dl), platelets <50,000, vasculitis (other than mild cutaneous vasculitis), including pulmonary hemorrhage, myocarditis, lupus pneumonitis, severe myositis (with muscle weakness, not just high enzymes), lupus enteritis (vasculitis), lupus pancreatitis, cholecystitis, lupus hepatitis, protein-losing enteropathy, malabsorption, orbital inflammation/myositis, severe keratitis, posterior severe uveitis/retinal vasculitis, severe scleritis, optic neuritis, anterior ischemic optic neuropathy (derived from the SELENA–SLEDAI flare index and the BILAG 2004 index)
Not severe SLE: not currently treated for above manifestations

* RA = rheumatoid arthritis; SpA = spondyloarthritis; AS = ankylosing spondylitis; PsA = psoriatic arthritis; JIA = juvenile idiopathic arthritis; SLE = systemic lupus erythematosus; THA = total hip arthroplasty; TKA = total knee arthroplasty; CNS = central nervous system; SELENA–SLEDAI = Safety of Estrogens in Lupus Erythematosus National Assessment version of the Systemic Lupus Erythematosus Disease Activity Index; BILAG = British Isles Lupus Assessment Group.

management of conflicts of interest and disclosures (https://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines), which includes Grading of Recommendations, Assessment, Development and Evaluations (GRADE) methodology and a framework for developing and presenting evidence (23,24) and adheres to Appraisal of Guidelines for Research and Evaluation (AGREE) criteria (25). The process for updating the 2017 guidelines began in 2021 (26). The populations included in this guideline are defined in Table 1 and are unchanged. Table 2 contains a list of the included drugs, along with their dosing intervals (reflecting the duration of effect), with the drugs newly added for this 2022 update denoted with footnotes. Brand names were used for newer medications that are likely to be unfamiliar to some orthopedists. Supplementary Appendix 1, available on the *Arthritis Care & Research* website at http://onlinelibrary.wiley.com/doi/10.1002/acr.24893, includes a detailed description of the methods. Briefly, 3 teams were formed: a Core Leadership Team, a Literature Review Team, and a Voting Panel. The Core Leadership Team (SMG, BDS, AY, and JAS) confirmed that the population, intervention, comparator, and outcomes (PICO) questions would be the same as the ones used for the 2017 guideline, with updated medication lists to include any therapies approved for use in the US as of August 26, 2021, the stop date of our literature review (see Table 2 for medication list and Supplementary Appendix 2, available on the *Arthritis Care & Research* website at http://onlinelibrary.wiley.com/doi/10.1002/acr.24893, for the PICO list, including outcomes; see Supplementary Appendices 3 and 4, available at http://onlinelibrary.wiley.com/doi/10.1002/acr.24893, for the search strategies and study selection process, respectively).

The Literature Review Team performed updates of the systematic literature review for each PICO, graded the quality of evidence (high, moderate, low, very low), and produced the evidence report (see Supplementary Appendix 5, available on the *Arthritis Care & Research* website at http://onlinelibrary.wiley.com/doi/10.1002/acr.24893). The systematic literature review was updated by searching for relevant published literature from March 6, 2016 to August 26, 2021, because the previous systematic literature review for the 2017 guideline was performed from January 1, 1980 through March 6, 2016. Although the updated literature review added to the evidence report, the overall quality of the evidence remained low due to indirect evidence or small numbers of included cases. Because the overall quality of evidence was low, we included a review of the background risk for adverse events associated with THA or TKA in patients with RA, SpA, JIA, or SLE that is independent of use of the medications of interest to give context to our deliberations. Severe SLE is defined in Table 1 and refers to those patients with severe organ manifestations such as nephritis. We did not repeat our search for additional indirect evidence regarding medication risks associated with our drugs of interest; included medications are listed in Table 2.

The Voting Panel included 2 patients who have undergone arthroplasty surgery and who participated in the 2017 guideline's Patient Panel, one of whom participated in the previous Voting Panel. The panel reviewed evidence summaries from both the 2017 project and this update and discussed and voted on recommendation statements. The recommendation regarding anifrolumab and voclosporin was voted on via email. A recommendation could be either in favor of or against the proposed intervention and either strong or conditional. Consensus required ≥70% agreement on both direction (for or against) and strength (strong or conditional) for each recommendation. Per GRADE methodology, a recommendation is categorized as strong if the panel is very confident that the benefits of an intervention clearly outweigh the harms (or vice versa); a conditional recommendation denotes uncertainty regarding the balance of benefits and harms, such as when the evidence quality is low or very low, or when the decision is more sensitive to individual patient preferences, or when costs are expected to impact the decision. Thus, conditional recommendations refer to decisions in which incorporation of patient preferences is a particularly essential element of decision-making.

Rosters of the Core Leadership Team, Literature Review Team, and Voting Panel are included in Supplementary Appendix 6, available on the *Arthritis Care & Research* website at http://onlinelibrary.wiley.com/doi/10.1002/acr.24893. This study did not involve human subjects, and therefore, approval from Human Studies Committees was not required.

Table 2. Medications included in this 2022 guideline update*

	Dosing interval	Recommended timing of surgery since last medication dose
Medications to continue through surgery		
DMARDs: continue these medications through surgery (all patients)		
Methotrexate	Weekly	Anytime
Sulfasalazine	Once or twice daily	Anytime
Hydroxychloroquine	Once or twice daily	Anytime
Leflunomide (Arava)	Daily	Anytime
Doxycycline	Daily	Anytime
Apremilast (Otezla)	Twice daily†	Anytime†
Severe SLE-specific medications: continue these medications in the perioperative period in consultation with the treating rheumatologist‡		
Mycophenolate mofetil	Twice daily	Anytime
Azathioprine	Daily or twice daily	Anytime
Cyclosporine	Twice daily	Anytime
Tacrolimus	Twice daily (IV and PO)	Anytime
Rituximab (Rituxan)	IV every 4–6 months†	Month 4–6†
Belimumab SC (Benlysta)	Weekly†	Anytime†
Belimumab IV (Benlysta)	Monthly†	Week 4†
Anifrolumab (Saphnelo)§	IV every 4 weeks†	Week 4†
Voclosporin (Lupkynis)§	Twice daily†	Continue†
Medications to withhold prior to surgery¶		
Biologics: withhold these medications through surgery		
Infliximab (Remicade)	Every 4, 6, or 8 weeks	Week 5, 7, or 9
Adalimumab (Humira)	Every 2 weeks	Week 3
Etanercept (Enbrel)	Every week	Week 2
Golimumab (Simponi)**	Every 4 weeks (SQ) or every 8 weeks (IV)	Week 5 Week 9
Abatacept (Orencia)	Monthly (IV) or weekly (SC)	Week 5; week 2
Certolizumab (Cimzia)	Every 2 or 4 weeks	Week 3 or 5
Rituximab (Rituxan)	2 doses 2 weeks apart every 4–6 months	Month 7
Tocilizumab (Actemra)	Every week (SC) or every 4 weeks (IV)	Week 2; week 5
Anakinra (Kineret)	Daily	Day 2
IL-17 secukinumab (Cosentyx)	Every 4 weeks	Week 5
Ustekinumab (Stelara)	Every 12 weeks	Week 13
Ixekizumab (Taltz)§	Every 4 weeks†	Week 5†
IL-23 guselkumab (Tremfya)§	Every 8 weeks†	Week 9†
JAK inhibitors: withhold this medication 3 days prior to surgery#		
Tofacitinib (Xeljanz)	Daily or twice daily†	Day 4†
Baricitinib (Olumiant)§	Daily†	Day 4†
Upadacitinib (Rinvoq)§	Daily†	Day 4†
Not severe SLE: withhold these medications 1 week prior to surgery		
Mycophenolate mofetil	Twice daily	1 week after last dose†
Azathioprine	Daily or twice daily	1 week after last dose
Cyclosporine	Twice daily	1 week after last dose†
Tacrolimus	Twice daily (IV and PO)	1 week after last dose†
Rituximab (Rituxan)	Every 4–6 months	Month 7
Belimumab IV (Benlysta)	Monthly†	Week 5†
Belimumab SC (Benlysta)	Weekly†	Week 2†

* Dosing intervals obtained from prescribing information provided online by pharmaceutical companies. Adapted from the 2017 American College of Rheumatology/American Association of Hip and Knee Surgeons guideline (26). DMARDs = disease-modifying antirheumatic drugs; SLE = systemic lupus erythematosus; IV = intravenous; PO = by mouth; SC = subcutaneous; IL-17 = interleukin-17.
** Correction added on 24 August 2022, after first online publication on 20 June 2022. One of the biologic medications to withhold prior to surgery was omitted from Table 2. Golimumab (Simponi) and the corresponding dosing/timing have been added.
† Recommendation that has changed since 2017.
‡ Severe SLE indicates organ-threatening disease.
§ Drug added for 2022 update.
¶ For patients with rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, or all SLE for whom antirheumatic therapy was withheld prior to undergoing total joint arthroplasty, antirheumatic therapy should be restarted once the wound shows evidence of healing, any sutures/staples are out, there is no significant swelling, erythema, or drainage, and there is no ongoing nonsurgical site infection, which is typically ~14 days.
# Recommendation pertains to infection risk and does not account for risk of cardiac events or venous thromboembolism.

RESULTS/RECOMMENDATIONS

How to interpret the recommendations

1. All recommendations in this guideline are conditional due to the quality of the evidence (see bolded statements in Table 3). A conditional recommendation means that the desirable effects of following the recommendation probably outweigh the undesirable effects, so the course of action would apply to the majority of the patients but may not apply to all patients. Because of this, conditional recommendations are preference sensitive and always

Table 3. Recommendations for perioperative management of antirheumatic drug therapy in patients with inflammatory arthritis and those with systemic lupus erythematosus (SLE) undergoing elective total hip arthroplasty (THA) or total knee arthroplasty (TKA)*

Recommendation/strength of recommendation	Level of evidence
For patients with RA, AS, PsA, JIA, or all SLE undergoing THA or TKA, continuing the usual dosing of the following DMARDs through surgery is **conditionally** recommended: methotrexate, leflunomide, hydroxychloroquine, sulfasalazine, and/or apremilast.†	Low to moderate
For patients with RA, AS, PsA, or JIA undergoing THA or TKA, withholding all biologics, including rituximab, prior to surgery and planning the surgery after the next dose is due is **conditionally** recommended.	Low
For patients with RA, AS, PsA, or JIA undergoing THA or TKA, withholding tofacitinib, baricitinib, and upadacitinib for at least 3 days prior to surgery is **conditionally** recommended.‡	Low
For patients with SLE (not severe) undergoing THA or TKA, withholding the current dose of mycophenolate mofetil, mycophenolic acid, azathioprine, cyclosporine, mizoribine, or tacrolimus 1 week prior to surgery is **conditionally** recommended.	Low
For patients with SLE (not severe) undergoing THA or TKA, withholding the usual dose of belimumab and rituximab prior to surgery is **conditionally** recommended.	Low
For patients with severe SLE who have been deemed appropriate to undergo THA or TKA, continuing the usual dose of mycophenolate mofetil, mycophenolic acid (Myfortic), azathioprine, mizoribine, cyclosporine, or tacrolimus, anifrolumab, and voclosporin through surgery is **conditionally** recommended.‡	Low
For patients with severe SLE undergoing THA or TKA, continuing belimumab and planning surgery in the last month of the dosing cycle of rituximab is **conditionally** recommended.‡	Low
For patients with RA, AS, PsA, or all SLE for whom antirheumatic therapy was withheld prior to undergoing TJA, antirheumatic therapy should be restarted once the wound shows evidence of healing, any sutures/staples are out, there is no significant swelling, erythema, or drainage, and there is no ongoing nonsurgical site infection, which is typically ~14 days, is **conditionally** recommended.	Low
For patients with RA, AS, PsA, or all SLE undergoing THA or TKA who are receiving glucocorticoids for their rheumatic condition, continuing their current daily dose of glucocorticoids rather than administering supraphysiologic doses of glucocorticoids on the day of surgery is **conditionally** recommended.	Low

* RA = rheumatoid arthritis; AS = ankylosing spondylitis; PsA = psoriatic arthritis; JIA = juvenile idiopathic arthritis; DMARDs = disease-modifying antirheumatic drugs; TJA = total joint arthroplasty.
† Apremilast is a change from the prior recommendation.
‡ Indicates a change from the prior recommendation.

warrant a shared decision-making approach. No strong recommendations are made in this guideline, although no recommendation achieved <80% of the vote, and 4 of the votes were unanimous.

2. For each recommendation, a summary of the supporting evidence or conditions is provided.

3. Therapies that were approved after the end of the original systematic literature review on March 6, 2016 through August 2021 are included in these updated recommendations. Therapies approved after the end of the updated systematic review (March 6, 2016 to August 26, 2021) are not included in these recommendations.

4. PICO questions were combined in the final recommendations for clarity.

Recommendations

For patients with RA, AS, PsA, JIA, or all SLE undergoing elective THA or TKA, continuing the usual dosing of the following disease-modifying antirheumatic drugs (DMARDs) through surgery is conditionally recommended: methotrexate, leflunomide, hydroxychloroquine, sulfasalazine, and/or apremilast.

This conditional recommendation now includes apremilast, but it is otherwise unchanged from the 2017 guideline. Four observational studies provided additional indirect evidence to the previous systematic literature review and found no relationship between the included drugs and the risk of postoperative infections, although the number of included cases and events were low (11,27–29). Patients with a history of severe or recurrent infections or prior prosthetic joint infection may elect to withhold these medications before surgery.

For patients with RA, AS, PsA, or JIA undergoing elective THA or TKA, withholding all biologics, including rituximab, prior to surgery and planning the surgery after the next dose is due is conditionally recommended.

This recommendation no longer includes patients with SLE, who are addressed separately (see below for rationale) but has not otherwise changed. Table 2 contains the included medications.

This recommendation is conditional because the evidence is indirect and there is a lack of a comparator group in the included studies (27,30). This recommendation was informed by additional new evidence from 2 studies that used administrative claims data to accurately capture the timing of infliximab or abatacept use before THA or TKA and to evaluate associations between biologics timing and outcomes (30,31). In both studies, there was no difference in postoperative outcomes when comparing short medication interruptions of ~1 dosing interval to longer interruptions. Results were similar in an additional study evaluating infliximab or abatacept timing before other types of surgery (32). These studies also showed no difference in outcomes in patients receiving infliximab or abatacept within 1 dosing interval before

surgery, although patients receiving intravenous abatacept within 2 weeks of surgery (one-half of a dosing interval) had a numerically higher rate of adverse events that was not statistically significant (31).

Planning the surgery after the end of the dose interval was favored because active drug levels would be low. For example, for rituximab, dosed every 6 months, surgery should be planned during month 7, and for adalimumab, dosed every 2 weeks, surgery should be planned for week 3 (see Table 2 for drug dosing intervals). Patients and their physicians might elect surgery within the dosing cycle if their symptoms from the operative joint are severe and the anticipated pain relief provided by surgery outweighs the possible risk of infection as may occur with advanced osteonecrosis. In addition, those patients whose disease has been challenging to control may also elect to continue their medications rather than risk loss of disease control, as this may occur when medications are withheld.

For patients with RA, AS, PsA, or JIA undergoing THA or TKA, withholding tofacitinib, baricitinib, and upadacitinib for at least 3 days prior to surgery is conditionally recommended.

This conditional recommendation was changed from the prior guideline. For the previous guideline, while the short serum half-life of tofacitinib was known, concern for a longer duration of the immune effect prompted the recommendation to withhold tofacitinib for 7 days prior to surgery. The new recommendation was informed by trial data demonstrating rapid increases in disease activity after interrupting tofacitinib therapy, suggesting a rapid reversal of the immunosuppressive effects, so the recommendation was changed to withhold tofacitinib for 3 days prior to surgery (33). The serum half-life of the newer JAK inhibitors is similar to that of tofacitinib. However, patients and their physicians might withhold JAK inhibitors for a longer period if a patient has a history of infections or a prior prosthetic joint infection. This recommendation does not pertain to the risk of a cardiac event or a venous thromboembolic event (VTE) potentially associated with JAK inhibitors.

For patients with SLE (not severe) undergoing THA or TKA, withholding the current dose of mycophenolate mofetil, mycophenolic acid, azathioprine, cyclosporine, mizoribine, or tacrolimus 1 week prior to surgery is conditionally recommended.

This recommendation remains unchanged from the prior guideline. Patients with frequent flares or SLE that is difficult to control might continue their medications, but the majority could be followed up closely after surgery to address a flare.

For patients with SLE (not severe) undergoing THA or TKA, withholding the usual dose of belimumab and rituximab prior to surgery is conditionally recommended.

This recommendation is unchanged from the prior guideline. Patients with SLE that is not severe would not be at risk for permanent organ damage should they flare. In addition, nonsevere SLE patients could be followed up closely after surgery, and an intervention could be made to treat a flare as needed. Patients with frequent flares or SLE that is difficult to control might choose to continue their medications in a shared decision-making approach with their physicians, but the majority could be followed up closely after surgery to address a flare.

For patients with severe SLE (Table 1) who have been deemed appropriate to undergo THA or TKA, continuing the usual dose of mycophenolate mofetil, mycophenolic acid (Myfortic), azathioprine, mizoribine, cyclosporine, or tacrolimus, anifrolumab, and voclosporin through surgery is conditionally recommended.

This recommendation has changed with the addition of anifrolumab and voclosporin, recently introduced medications for severe SLE. These medications should be continued through surgery. There were no new data available to update this recommendation, so the guidance reflects the concern about disease flares and the risk of organ damage in severe SLE that could be precipitated by medication withdrawal; although postoperative adverse events are linked to disease severity, they have not been clearly associated with medication use. As noted in the previous guideline, the patient's rheumatologist should be consulted regarding medication management. A patient with severe SLE who has been stable for >6 months or who has a history of recurrent or severe infections might discontinue the medications in the perioperative period.

For patients with severe SLE undergoing THA or TKA, continuing belimumab and planning surgery in the last month of the dosing cycle of rituximab is conditionally recommended.

In the prior guideline, rituximab was included in the recommendations with other biologics, but increased use for SLE treatment, the long dosing interval for rituximab, and the indication of belimumab as therapy for severe SLE manifestations has informed this change. Surgery should be planned at the end of the dosing cycle, typically during month 5 or 6 for patients receiving rituximab every 6 months, and to avoid disruptions of therapy rather than wait longer, given the long dosing interval for rituximab. The panel noted that rituximab is used in SLE without an indication approved by the US Food and Drug Administration (FDA) but also noted that it has been included in SLE treatment guidelines (34). In addition, there is a risk of disease flares in patients with severe SLE with organ damage if therapy is interrupted. Situations such as prior severe infections and/or SLE that has been stable for >6 months might prompt the clinician to withhold rituximab for a longer period. Recent studies describe an increased risk of adverse events associated with SLE that appears to be more significant for THA than TKA, but there are no strong data to suggest that these outcomes are related to medication management (34–37).

This recommendation has changed since the prior guideline in part because of the additional indication for the use of belimumab in severe SLE including nephritis, as well as increased

comfort with belimumab among clinicians and patients given its widespread use, low infection risk described in clinical trials, and inclusion in SLE treatment guidelines (34,38,39). The panel remained concerned about disruptions of successful treatment regimens in patients with severe SLE given the potential for severe organ damage, although belimumab might be withheld in stable patients with a history of prior infections.

For patients with RA, AS, PsA, or all SLE for whom antirheumatic therapy was withheld prior to undergoing total joint arthroplasty, antirheumatic therapy should be restarted once the wound shows evidence of healing, any sutures/staples are out, there is no significant swelling, erythema, or drainage, and there is no ongoing nonsurgical site infection, which is typically ~14 days after surgery, is conditionally recommended.

Drugs should be restarted based on the clinical status of the patient and the status of the healing wound. Although there was additional evidence to support this recommendation from the literature review, it was indirect and of very low quality across the critical outcomes. Patients with nonrheumatic diseases were included, or the study did not include a comparator group. In one study using a large Medicare data set, outcomes were better in patients who restarted infliximab within 4 weeks after surgery compared to those who restarted later, but the authors noted that this was likely because postoperative complications led to delays in restarting therapy (30).

Patients and their physicians might elect longer periods of not taking medication given a history of prior severe infections or a history of a prior prosthetic joint infection.

For patients with RA, AS, PsA, or all SLE undergoing THA or TKA who are receiving GCs for their rheumatic condition, continuing their current daily dose of GCs rather than administering supraphysiologic doses of GCs on the day of surgery is conditionally recommended.

This recommendation is unchanged from the previous guideline, with 2 new studies considered. One study found no significant association of supraphysiologic ("stress dose") GC doses with adverse events in SLE patients undergoing THA or TKA, but the sizes of the patient groups were small (35). Another study of 432 patients with RA who underwent THA and TKA concluded that patients with higher GC exposure were more likely to have hyperglycemia and other complications and that the risk of short-term complications is increased by 8.4% for every 10-mg increase in GC dose, and a lower cumulative GC dose was not associated with hypotension (40). Exceptions to this recommendation are unchanged. However, wound healing may be affected by use of low-dose (<5 mg/day) GCs when the cumulative dose is high, which may also contribute to perioperative infection risk. This recommendation does not refer to patients with JIA who may have received GCs during childhood developmental stages or to patients receiving GCs to treat primary adrenal insufficiency or primary hypothalamic disease, all of whom may require supraphysiologic doses of GCs to maintain hemodynamic stability.

DISCUSSION

We have updated the 2017 ACR/AAHKS guideline for the perioperative management of DMARDs, biologics, and GCs for adult patients with RA, SpA including AS and PsA, JIA, and SLE undergoing elective THA or TKA. This guideline is intended for use by clinicians and patients and balances the risk of flares of disease when medications are withheld versus infection risk attributed to the medications when they are continued. This update adds new medications introduced and reviews the studies published since the 2017 ACR/AAHKS guideline that have informed our recommendations. The scope of the guideline has not changed and addresses when to withhold and when to restart disease-modifying therapies, as well as perioperative GC management. Although we included patients in our Voting Panel, we did not reinstate the Patient Panel due to the risk associated with the COVID-19 pandemic, and because we thought it was unlikely that patients' priorities regarding the risk of flare versus the risk of infection would have changed. The updated medication list includes medications introduced to treat RA and SpA, including AS and PsA. We have included perioperative management recommendations for the recently introduced JAK-targeted therapies, baricitinib and upadacitinib, in addition to tofacitinib. We have included new management recommendations for the interleukin-17 (IL-17) blocking agent ixekizumab, the IL-23–blocking drug, guselkumab, and the novel synthetic DMARD apremilast. Anifrolumab, approved by the FDA on July 30, 2021, and voclosporin, approved January 22, 2021, were included in this guideline, although there is no information regarding their use in the perioperative period. They increase the risk of infection, and therefore the use of these medications in patients with severe SLE would merit review by the treating rheumatologist in consideration of surgery. The Voting Panel agreed with their inclusion via email voting.

This guideline is informed by cohort studies including pharmacoepidemiologic studies using large administrative databases. To our knowledge, there have been no randomized controlled trials since the publication of the prior ACR/AAHKS guideline in 2017, so much of the data supporting these recommendations remains largely indirect or of low quality. Similar to the last guideline, the major limitation remains the paucity of high-quality direct evidence regarding the added risk of infection from medication use at the time of THA or TKA; therefore, these recommendations continue to rely on indirect studies describing results in patients without rheumatic diseases or on assumptions or conclusions extrapolated from nonsurgical studies. An additional limitation of this guideline is the lack of participation from other orthopedic surgical specialties such as spine or foot and ankle. Moreover, our literature review focused only on THA and TKA, so concerns

of other surgical specialists may have not been addressed by our focused assessment of THA and TKA. Therefore, we are unable to generalize our recommendations to rheumatic disease patients undergoing other orthopedic surgical procedures, as well as non-orthopedic surgery. However, the principles underlying our recommendations may provide a framework to apply in other surgical settings.

A strength of this guideline is the robust collaboration between orthopedic hip and knee surgeons and rheumatologists, as well as the inclusion of patients, epidemiologists, and specialists in infectious diseases who represent other stakeholders for this project. This multidisciplinary collaboration facilitated the uptake and dissemination of the prior guideline, and it is anticipated that these recommendations will be similarly distributed and used to guide busy clinicians and their patients at the time of THA and TKA. GRADE methodology supports consensus-based recommendations that can be reached based on low-quality evidence across the critical outcomes and transparently rates the strength of the recommendation as well as the quality of the evidence supporting the recommendation (24,41). Because most of the evidence informing this guideline is indirect and/or of low quality, all of the recommendations are conditional. Nonetheless, consensus of the Voting Panel was high. Four recommendations received 100% agreement, and none achieved <80% agreement.

This guideline does not address perioperative prophylaxis or treatment of VTEs or perioperative cardiac assessment, as these are addressed in several other focused publications. JAK inhibitors as a class carry an increased risk of VTE, which is a black box warning from the FDA, which more recently issued a warning regarding increased cardiovascular risk (42). Future research should address an assessment of the perioperative cardiac and VTE risks associated with JAK inhibitors and other factors such as disease activity for which there is no direct evidence.

Perioperative management of rituximab has been a challenge given the long dosing interval of 6 months and the recognized risk of severe infection linked to its use (43–46). In this updated guideline, we have separated the perioperative use of rituximab in SLE from the perioperative management of rituximab in other diseases (46). Although rituximab has an FDA indication for RA, but not for SLE, the 2019 European Alliance of Associations for Rheumatology recommendations for the management of SLE include use of rituximab, providing an additional rationale for our change to separate the recommendations for RA and other rheumatic conditions from those for severe SLE (34). Our recommendations are linked to drug dosing intervals given our assumption that the dosing interval reflects the period of immunosuppression; however, infection risk in patients treated with rituximab may be unrelated to the rituximab dosing interval and is increased in those with hypogammaglobulinemia (47,48). Additional research is needed to increase understanding of the factors contributing to infection risk with rituximab therapy, such as duration of therapy or immunoglobulin levels at the time of surgery.

As previously, the recommendations that form this guideline are not treatment mandates. These recommendations will provide the backbone for a shared decision-making process between patient and physician regarding perioperative medication management around the time of surgery. The previous Patient Panel provided critical insight into the priorities of patients around the time of THA and TKA and the importance of open discussion and consultation between the perioperative physician, the orthopedic surgeon, and the rheumatologist. One patient representative on the current Voting Panel noted the anxiety that patients experience around changes to their medication regimens and urged clinicians to be cognizant of this important issue. Although not all scenarios can be addressed in the scope of a document such as this guideline, the most common scenarios are included, and these recommendations should supplement the usual perioperative clinical assessment, risk benefit discussions, and management for clinical optimization prior to surgery.

We continue to support ongoing research to better inform perioperative management of medications used commonly in rheumatic diseases. While we have added to our information base regarding GC management and the timing of biologic infusion therapy, we still lack high-level data from randomized controlled trials to provide clearer answers to the important questions addressed in the guideline. Data concerning traditional synthetic DMARDs should be updated with randomized controlled trials, and data regarding perioperative management of biologics also needs more definitive study. Patients with rheumatic diseases have higher rates of concomitant metabolic syndrome and cardiac disease and may also be at potentially higher risk of perioperative cardiac and/or thromboembolic events. Therefore, consideration of the role of comorbidities and the interaction with antirheumatic therapy should also be pursued.

In summary, this guideline provides an update to the ACR/AAHKS 2017 guideline to provide clinicians and patients information about risks and benefits regarding management of perioperative antirheumatic medication to inform decisions prior to THA and TKA. We have updated our evidence base through our search of the current literature and assessed that information through the lens of our clinical expertise and the perspectives of the patients who have participated in this process. We acknowledge the gaps in our information base and intend to continue to fill those gaps as more research is available.

ACKNOWLEDGMENTS

We thank the ACR staff, including Regina Parker for assistance in coordinating the administrative aspects of the project and Cindy Force for assistance with manuscript preparation. We thank Janet Waters for her assistance in developing the literature search strategy as well as performing the initial literature search and update searches.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be submitted for publication. Dr. Goodman had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Guidelines and recommendations developed and/or endorsed by the American College of Rheumatology (ACR) are intended to provide guidance for particular patterns of practice and not to dictate the care of a particular patient. The ACR considers adherence to the recommendations within this guideline to be voluntary, with the ultimate determination regarding their application to be made by the physician in light of each patient's individual circumstances. Guidelines and recommendations are intended to promote beneficial or desirable outcomes but cannot guarantee any specific outcome. Guidelines and recommendations developed and endorsed by the ACR are subject to periodic revision as warranted by the evolution of medical knowledge, technology, and practice. ACR recommendations are not intended to dictate payment or insurance decisions. These recommendations cannot adequately convey all uncertainties and nuances of patient care.

The American College of Rheumatology is an independent, professional, medical and scientific society that does not guarantee, warrant, or endorse any commercial product or service.

This article is published simultaneously in *Arthritis & Rheumatology* and the *Journal of Arthroplasty*.

Objective. **This collaboration between the American College of Rheumatology and the American Association of Hip and Knee Surgeons developed an evidence-based guideline for the perioperative management of antirheumatic drug therapy for adults with rheumatoid arthritis (RA), spondyloarthritis (SpA) including ankylosing spondylitis and psoriatic arthritis, juvenile idiopathic arthritis (JIA), or systemic lupus erythematosus (SLE) undergoing elective total hip (THA) or total knee arthroplasty (TKA).**

Methods. **A panel of rheumatologists, orthopedic surgeons specializing in hip and knee arthroplasty, and methodologists was convened to construct the key clinical questions to be answered in the guideline. A multi-step systematic literature review was then conducted, from which evidence was synthesized for continuing versus withholding antirheumatic drug therapy and for optimal glucocorticoid management in the perioperative period. A Patient Panel was convened to determine patient values and preferences, and the Grading of Recommendations Assessment, Development and Evaluation methodology was used to rate the quality of evidence and the strength of recommendations, using a group consensus process through a convened Voting Panel of rheumatologists and orthopedic surgeons. The strength of the recommendation reflects the degree of certainty that benefits outweigh harms of the intervention, or vice versa, considering the quality of available evidence and the variability in patient values and preferences.**

Results. **The guideline addresses the perioperative use of antirheumatic drug therapy including traditional disease-modifying antirheumatic drugs, biologic agents, tofacitinib, and glucocorticoids in adults with RA, SpA, JIA, or SLE who are undergoing elective THA or TKA. It provides recommendations regarding when to continue, when to withhold, and when to restart these medications, and the optimal perioperative dosing of glucocorticoids. The guideline includes 7 recommendations, all of which are conditional and based on low- or moderate-quality evidence.**

Conclusion. **This guideline should help decision-making by clinicians and patients regarding perioperative antirheumatic medication management at the time of elective THA or TKA. These conditional recommendations reflect the paucity of high-quality direct randomized controlled trial data.**

INTRODUCTION

Although the wide utilization of disease-modifying antirheumatic drugs (DMARDs) and biologic agents has improved the quality of life for patients with rheumatoid arthritis (RA), spondyloarthritis (SpA), juvenile idiopathic arthritis (JIA), or systemic lupus erythematosus (SLE), rates of total hip arthroplasty (THA) and total knee arthroplasty (TKA) remain high (1–6). Patients with rheumatic conditions report significant improvement in pain and function after THA or TKA, yet critical outcomes such as infection, dislocation, and readmission are reported to be higher for patients with RA, SpA, or SLE (7–10) compared to patients with osteoarthritis. At the time of arthroplasty in a high-volume orthopedic hospital, 46% of RA patients were receiving biologic agents, 67% were receiving nonbiologic DMARDs, and 25% were receiving glucocorticosteroids, while 75% of patients with SLE were receiving immunosuppressive medications, and 15% were receiving glucocorticosteroids. The optimal strategy to manage these medications is not known (11–14). Inherent risk factors for infection, such as overall disability and disease activity/severity, may not be modifiable, but the optimal perioperative management of immunosuppressant therapy around the time of arthroplasty may present an opportunity to mitigate risk (15–19).

In this setting, clinicians require guidance regarding perioperative management of antirheumatic drug therapy. Direct evidence, however, which addresses perioperative management is sparse (20,21). To our knowledge, there are no randomized controlled trials (RCTs) evaluating the cessation and reintroduction of biologic agents at the time of THA or TKA. The relevant outcomes considered for these guidelines are the potential increase in infection risk added by the medications versus the risk of disease

Submitted for publication September 26, 2016; accepted in revised form April 28, 2017.

Significance & Innovations

- Patients with rheumatic diseases undergoing total hip arthroplasty (THA) and total knee arthroplasty (TKA) are at increased risk for periprosthetic joint infection.
- Appropriate management of antirheumatic medication in the perioperative period may provide an important opportunity to mitigate risk.
- Nonbiologic disease-modifying antirheumatic drugs may be continued throughout the perioperative period in patients with rheumatic diseases who are undergoing elective THA and TKA.
- Biologic medications should be withheld as close to 1 dosing cycle as scheduling permits prior to elective THA and TKA and restarted after evidence of wound healing, typically 14 days, for all patients with rheumatic diseases.

flare when the medications are withheld. This guideline pertains only to adult patients with RA, SpA including ankylosing spondylitis (AS) and psoriatic arthritis (PsA), JIA, or SLE, who are undergoing elective THA or TKA, and incorporates patient preferences.

This guideline addresses management of antirheumatic medication in those adult patients with diagnoses of RA, SpA, JIA, or SLE, but is not limited to those who meet classification criteria. This guideline is to be used for those who have elected and have been deemed appropriate candidates for THA or TKA. We would caution against extrapolation of this guideline to other orthopedic procedures until further data are available.

This guideline is intended for use by clinicians, including orthopedists, rheumatologists, and other physicians performing perioperative risk assessment and evaluation, as well as patients. The guideline addresses common clinical situations, but may not apply in all exceptional or unusual situations. It is imperative that open and informed communication between the patient, orthopedic surgeon, and rheumatologist takes place. In addition, while cost is a relevant factor in health care decisions, it was not considered in this project.

The populations included in this guideline are shown in Table 1 (22–24). Figure 1 contains a list of the drugs included in the evaluation, along with their dosing intervals, as the Panel determined that the dosing interval and route were more relevant for this guideline because they reflect the duration of effect.

This guideline does not address indications for THA or TKA, medical decisions unrelated to antirheumatic drug therapy, choice of implant, surgical approach, or perioperative evaluation and management of concurrent disease, such as that affecting the cervical spine of patients with RA. Although patients with RA, SpA, JIA, or SLE should be assessed for risk of venous thromboembolism and major acute coronary event (8,25), this guideline does not address cardiac risk assessment or perioperative venous thromboembolism prophylaxis; both are covered in existing guidelines (26–29).

METHODS

Overall methodology. This guideline follows the American College of Rheumatology (ACR) guideline development process (http://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines), using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology to rate the quality of the available evidence and to develop the recommendations (30). Conflicts of interest and disclosures were

Table 1. Populations included in the guideline*

Populations†
Adults age ≥18 years diagnosed with rheumatoid arthritis, spondyloarthritis including ankylosing spondylitis and psoriatic arthritis, juvenile idiopathic arthritis, or SLE (see below), who are deemed to be appropriate surgical candidates, undergoing elective total hip arthroplasty or total knee arthroplasty, and who are treated with antirheumatic drug therapy at the time of surgery.
SLE
SLE includes patients with severe or not severe SLE (defined below), and who are in optimal condition for surgery:
Severe SLE
Currently treated (induction or maintenance) for severe organ manifestations: lupus nephritis, central nervous system lupus, severe hemolytic anemia (hemoglobin <9.9), platelets <50,000/ml, vasculitis (other than mild cutaneous vasculitis), including pulmonary hemorrhage, myocarditis, lupus pneumonitis, severe myositis (with muscle weakness, not just high enzymes), lupus enteritis (vasculitis), lupus pancreatitis, cholecystitis, lupus hepatitis, protein-losing enteropathy, malabsorption, orbital inflammation/myositis, severe keratitis, posterior severe uveitis/retinal vasculitis, severe scleritis, optic neuritis, anterior ischemic optic neuropathy (derived from the SELENA–SLEDAI Flare Index and BILAG 2004) (22–24).
Not severe SLE
Not currently treated for manifestations listed under Severe SLE.

* SLE = systemic lupus erythematosus; SELENA–SLEDAI = Safety of Estrogens in Lupus Erythematosus National Assessment version of the Systemic Lupus Erythematosus Disease Activity Index; BILAG = British Isles Lupus Assessment Group.
† All patients carrying the diagnoses listed, without restriction to those meeting classification criteria.

DMARDs: CONTINUE these medications through surgery.	**Dosing Interval**	**Continue/Withhold**
Methotrexate	Weekly	Continue
Sulfasalazine	Once or twice daily	Continue
Hydroxychloroquine	Once or twice daily	Continue
Leflunomide (Arava)	Daily	Continue
Doxycycline	Daily	Continue
BIOLOGIC AGENTS: STOP these medications prior to surgery and schedule surgery at the end of the dosing cycle. RESUME medications at minimum 14 days after surgery in the absence of wound healing problems, surgical site infection, or systemic infection.	**Dosing Interval**	**Schedule Surgery (relative to last biologic agent dose administered) during**
Adalimumab (Humira)	Weekly or every 2 weeks	Week 2 or 3
Etanercept (Enbrel)	Weekly or twice weekly	Week 2
Golimumab (Simponi)	Every 4 weeks (SQ) or every 8 weeks (IV)	Week 5 Week 9
Infliximab (Remicade)	Every 4, 6, or 8 weeks	Week 5, 7, or 9
Abatacept (Orencia)	Monthly (IV) or weekly (SQ)	Week 5 Week 2
Certolizumab (Cimzia)	Every 2 or 4 weeks	Week 3 or 5
Rituximab (Rituxan)	2 doses 2 weeks apart every 4-6 months	Month 7
Tocilizumab (Actemra)	Every week (SQ) or every 4 weeks (IV)	Week 2 Week 5
Anakinra (Kineret)	Daily	Day 2
Secukinumab (Cosentyx)	Every 4 weeks	Week 5
Ustekinumab (Stelara)	Every 12 weeks	Week 13
Belimumab (Benlysta)	Every 4 weeks	Week 5
Tofacitinib (Xeljanz): STOP this medication 7 days prior to surgery.	Daily or twice daily	7 days after last dose
SEVERE SLE-SPECIFIC MEDICATIONS: CONTINUE these medications in the perioperative period.	**Dosing Interval**	**Continue/Withhold**
Mycophenolate mofetil	Twice daily	Continue
Azathioprine	Daily or twice daily	Continue
Cyclosporine	Twice daily	Continue
Tacrolimus	Twice daily (IV and PO)	Continue
NOT-SEVERE SLE: DISCONTINUE these medications 1 week prior to surgery	**Dosing Interval**	**Continue/Withhold**
Mycophenolate mofetil	Twice daily	Withhold
Azathioprine	Daily or twice daily	Withhold
Cyclosporine	Twice daily	Withhold
Tacrolimus	Twice daily (IV and PO)	Withhold

Figure 1. Medications included in the 2017 American College of Rheumatology/American Association of Hip and Knee Surgeons Guideline for the Perioperative Management of Antirheumatic Medication in Patients with Rheumatic Diseases Undergoing Elective Total Hip or Total Knee Arthroplasty. Dosing intervals were obtained from prescribing information provided online by pharmaceutical companies. DMARDs = disease-modifying antirheumatic drugs; SQ = subcutaneous; IV = intravenous; SLE = systemic lupus erythematosus; PO = oral.

managed according to ACR policy (available at www.rheumatology.org/Portals/0/Files/Perioperative-Management-Guidelines-Disclosure-Summary.pdf). The full methods are presented in Supplementary Appendix 1 (available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23274/abstract).

Using GRADE, a recommendation can be either in favor of or against the proposed intervention and either strong or conditional (31,32). Much of the evidence was indirect, coming from nonsurgical studies, and all evidence was low to moderate quality (33,34). A strong recommendation indicates that most or almost all informed patients would choose the recommended action. Conditional recommendations are those in which the majority of the informed patients would choose to follow the recommended course of action, but a minority might not (35,36).

Teams involved. This project was a collaboration between the ACR and the American Association of Hip and Knee Surgeons (AAHKS). All participating teams contained representatives from both organizations, including a Core Leadership Team for project oversight (5 members), the Literature Review Team, who reviewed the literature and compiled the literature report, the Expert Panel, who helped frame the scope of the project, and the Voting Panel (consisting of orthopedic surgeons, rheumatologists, an infectious disease expert, an SLE expert, patient representatives, rheumatology methodologists, and a GRADE expert), who determined the final recommendations (for a complete listing of Panel and Team members see Supplementary Appendix 2 [available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23274/abstract]). Additionally, a Patient Panel consisting of 11 adults with RA or JIA, all of whom had undergone THA or TKA, reviewed the evidence and provided input on their values and preferences.

PICO (population/intervention/comparator/outcomes) question development and importance of outcomes. The Core Leadership Team initially drafted the project scope, key principles, and relevant clinical PICO questions, which were then presented to the Expert Panel, the Voting Panel, and the Literature Review Team for their review at a face-to-face meeting where the project plan was defined. The relevant topics addressed included: 1) Should antirheumatic medications be withheld prior to elective THA/TKA? 2) If they are withheld, when should they be stopped? 3) If withheld, when should they be restarted after surgery? 4) In patients receiving glucocorticoids, what dose should be administered at the time of surgery? The full list of PICO questions is shown in Supplementary Appendix 3 (http://onlinelibrary.wiley.com/doi/10.1002/acr.23274/abstract).

Direct high-quality RCT data available comparing the risk of THA or TKA in those receiving versus not receiving the medications of interest, or comparing the background risk of THA and TKA in the populations of interest, were sparse. To address this gap, 2 questions were included to inform the recommendations. The first asked, "What is the background risk for serious adverse events including infections, or hospitalization, associated with use of each of the candidate drugs in patients not undergoing surgery?" The second question asked, "What is the background risk of adverse events associated with THA or TKA, independent of use of candidate medications in the populations of interest?" The group determined that both superficial and deep surgical site infection (reported within the first year after surgery), non–surgical site infection (within 90 days of surgery), and disease flare were the most critical outcomes; other outcomes such as hospital readmission, death, and long-term arthroplasty outcome were also deemed relevant.

Systematic synthesis of the literature and evidence processing. Systematic literature searches were performed in Embase (searched since 1974), the Cochrane Library, and PubMed (searched since the mid-1960s) from January 1, 1980 through March 6, 2016. The search strategies were developed using the controlled vocabulary or thesauri language for each database: Medical Subject Headings (MeSH) for PubMed and Cochrane Library and Emtree terms for Embase (see Supplementary Appendix 4, available on the *Arthritis Care & Research* web site at http://onlinelibrary.wiley.com/doi/10.1002/acr.23274/abstract). Text words were used in PubMed and Embase, and keyword/title/abstract words in the Cochrane Library. Searches resulted in 2,230 total references (see Supplementary Appendix 5, http://onlinelibrary.wiley.com/doi/10.1002/acr.23274/abstract). A final search update was performed for the time period of January 1 to September 8, 2016, using the inclusive search terms of the disease states, coupled separately with "arthroplasty"; no randomized trials were identified that were relevant to the guideline. DistillerSR software (http://systematic-review.net/) was used to screen the literature search results grouped by their match with the pertinent PICO questions.

The Literature Review Team analyzed and synthesized data from eligible studies. Due to the lack of RCTs, we were unable to prepare GRADE Summary of Findings tables for most PICO questions. Microsoft Excel was used for abstracting data from observational studies. When available, the evidence summaries included the benefits and harms for outcomes of interest across studies, the relative effect (with 95% confidence interval [95% CI]), the number of participants, and the absolute effects. We rated the quality of evidence for each critical and important outcome as high, moderate, low, or very low quality, taking into account limitations of study design (including the risk of bias), inconsistency, indirectness, imprecision, and other considerations (including publication bias).

Moving from evidence to recommendations. The Patient Panel attached far greater importance to infection at the time of surgery than to flares. They were unable to precisely quantify the difference in value, noting that it was greater than 10:1.

The Voting Panel met to decide the final recommendations. The Panel discussed the evidence in the context of both their clinical experience and the input from the Patient Panel. The Panel voted anonymously, and 80% agreement defined the threshold for a recommendation; if 80% agreement was not achieved during an initial vote,

the Panel members held additional discussions before revoting. Considerations that led to rating down of quality of evidence included indirectness (much of the evidence came from RCTs outside of the surgical context, or from foot or spine procedures in which infection risks may vary markedly from THA or TKA); heterogeneity in baseline medication dose and duration, particularly relevant in studies addressing glucocorticoid "stress-dose" therapy; and imprecision associated with small sample size.

All recommendations were supported by more than 80% of the Panel, and all but 1 were supported unanimously. In some instances, the Panel combined PICO questions into 1 final recommendation. For recommendations to withhold a medication, a recommendation for the suggested timing of surgery in relation to the last drug-dose was included.

RESULTS/RECOMMENDATIONS

How to interpret the recommendations

1. All recommendations in this guideline are conditional due to the quality of the evidence (see bolded statements in Table 2). A conditional recommendation means that the desirable effects of following the recommendation probably outweigh the undesirable effects, so the course of action would apply to the majority of the patients, but may not apply to all patients. Because of this, conditional recommendations are preference sensitive and always warrant a shared decision-making approach. No strong recommendations are made in this guideline.
2. For each recommendation, a summary of the supporting evidence or conditions is provided.
3. Therapies that were approved after the original systematic literature review are not included in these recommendations.
4. PICO questions were combined in the final recommendations for clarity.

Recommendations

1. RA, SpA including AS and PsA, JIA, and SLE receiving nonbiologic DMARDs

Continue the current dose of methotrexate, leflunomide, hydroxychloroquine, and/or sulfasalazine for patients undergoing elective THA or TKA (Table 2).

This conditional recommendation was based on low- to moderate-quality evidence. A systematic review of literature, which included RCTs of continuing versus discontinuing DMARDs at the time of surgery, revealed that the risk of infections was in fact decreased, with continuing DMARDs having a relative risk (RR) of 0.39 (95% CI 0.17–0.91) (37,38). The evidence base is rated down from high to moderate for reduction in infection risk after orthopedic surgery when these drugs are continued, because of risk of bias. There is indirect evidence describing a low infection risk with these specific DMARDs in settings other than THA and TKA (39). This recommendation was based on infection risk, although flares are also less frequent after surgery in those who continue DMARDs, and the RRs of flares when DMARDs are continued versus stopped (RR 0.06 [95% CI 0.0–1.10]) were derived from low-quality evidence (37,40).

2. RA, SpA including AS and PsA, JIA, or SLE

Withhold all current biologic agents prior to surgery in patients undergoing elective THA or TKA, and plan the surgery at the end of the dosing cycle for that specific medication (Table 2).

This recommendation was based on evidence that was rated down in quality for indirectness, as no RCTs were performed in patients undergoing THA or TKA. We abstracted data from a systematic review of literature that included systematic reviews and meta-analyses of biologic agents versus placebo (and occasionally versus control treatment including nonbiologic DMARDs) in nonsurgical patients, which revealed that the risk of serious infections was increased with biologic agents, with most odds/hazards/risk ratios ~1.5 (range 0.61–8.87) and a higher risk of serious adverse events with most odds/hazards/risk ratios ~1.5 (range 0.33–2.54) (41–87). Our systematic review did not provide ample evidence that would support a differential risk of serious infection among available biologic agents (41–87). Because avoiding infection was significantly more important to patients than flares in the postoperative period, the Panel did not support separating biologic agents regarding infection risk in the perioperative period until further studies clarify and establish differences in risk (41–87). The literature review also revealed that the risk of postoperative infection complications after total joint arthroplasty (TJA) was increased in patients with RA nearly 2-fold, and deep infection complications increased by 1.5-fold (2,56); in SLE, overall postoperative complications were increased 1.3-fold, and septicemia by 2-fold (8), although medication use at the time of surgery was not always reported. In addition, a systematic review, meta-analysis, and network meta-analysis revealed that infection risk for biologic agents is strongly associated with high-dose therapy (higher dose than the standard) and may not be associated with low-dose biologic agents (42), so serum half-life may not correspond to the duration of the immunosuppressant effect. The dosing cycle was therefore chosen as more relevant in determining the withholding interval (88–91) and timing the surgery at the end of the dosing interval at the nadir of the drug effect.

With regard to patients with SLE, a systematic review of literature that included systematic reviews and meta-analyses of rituximab versus placebo (and occasionally versus control treatment including nonbiologic DMARDs) in nonsurgical patients with RA and SLE revealed the risk of serious infections with rituximab with a range of RRs from 0.66 to 0.73 (41,45), and a risk for all serious adverse events with a range of RRs from 0.85 (95% CI 0.62–1.17) to 0.89 (95% CI 0.7–1.14) (59,92). However, most data were indirect and the Panel considered these medications to be similar to tumor necrosis factor inhibitors used for the treatment of RA, which usually have a risk of infection. Moreover, rituximab is not approved by the US Food and Drug Administration (FDA) for treatment of SLE, and belimumab, although FDA-approved for use in SLE, has not been studied in manifestations of severe SLE (e.g.,

lupus nephritis), so the Panel recommended withholding these medications prior to surgery and planning the surgery for the end of the dosing cycle, due to the risk of infection and the paucity of data supporting perioperative benefit in SLE (93–95).

Observational studies reveal that patients with severe or active SLE have a higher risk of adverse events after surgery, but there is no approved role for these biologic agents for patients with severe SLE, including perioperative risk mitigation. SLE manifestations of rash and synovitis are the common clinical indications for belimumab (95,96), and are not thought to increase perioperative risk. There is no direct evidence, however, linking perioperative infection risk to the use of these biologic agents, and little is known about the association of surgical risk with biologic agents for patients with SLE. Since the duration of the immunologic effects of these drugs does not correspond to the serum level, the Panel based the recommendation on the dosing interval (88–91). The Patient Panel did not include patients with SLE, and they were reluctant to vote on SLE medication management strategies because they were uncertain about the value SLE patients would place on flares, which might be organ-threatening, compared to infection risk.

As an example, using this guideline, patients treated with adalimumab, routinely dosed at 2-week intervals, would plan their surgery in week 3, while patients treated with infliximab, when dosed every 8 weeks, would schedule their surgery in the week after the first withheld dose during week 9. Patients treated with rituximab every 6 months would schedule their surgery, when possible, at the week after the first withheld dose during month 7. Patients with SLE receiving belimumab, which is given every 4 weeks, would schedule their surgery during week 5.

3. RA, SpA including AS and PsA, or JIA

Withhold tofacitinib for at least 7 days prior to surgery in patients with RA, SpA including AS and PsA, or JIA undergoing THA or TKA (Table 2).

This recommendation was based on indirect evidence from systematic reviews and meta-analyses of tofacitinib versus placebo (and occasionally versus control treatment including nonbiologic DMARDs) in nonsurgical patients showing that the risk of serious infections was increased with tofacitinib, with an incidence rate of 2.91 (95% CI 2.27–3.74) (97) and higher risk of all infections, with an RR of 5.7 (95% CI 1.8–18.1) (48). Although this drug has an extremely short serum half-life, little is known about the duration of immunosuppression after the drug is withheld, although indirect translational data suggest that host defense returns to normal at 7 days. Therefore, the Panel recognized that the recommendation for the duration of withholding may change in the future, as physician and patient experience with this drug grows (41,47,48,51,77,79,97,98).

4. Severe SLE (as defined in Table 1)

Continue the current dose of methotrexate, mycophenolate mofetil, azathioprine, cyclosporine, or tacrolimus through the surgical period in all patients undergoing THA or TKA (Table 2).

There is a great deal of uncertainty and little published experience regarding risks associated with perioperative medication management in patients with severe SLE. There is, however, indirect evidence concerning organ transplant patients who continue anti-rejection therapy through the surgical period (99,100). The caveat to this analogy is that the time course of organ rejection after withholding immunosuppressant medication may be different from the time to SLE flare after withholding medications. These considerations led to the recommendation to continue the current dose of methotrexate, mycophenolate mofetil, azathioprine, cyclosporine, or tacrolimus through the surgical period in all patients with severe SLE. Nevertheless, the Panel felt that decisions regarding elective surgery in patients with severe SLE should be made on an individual basis with the patient's rheumatologist.

5. Not-severe SLE (as defined in Table 1)

Withhold the current dose of mycophenolate mofetil, azathioprine, cyclosporine, or tacrolimus 1 week prior to surgery in all patients undergoing THA or TKA (Table 2).

For patients with not-severe SLE, the time course to flares after withholding medications is not known, while there is a known infection risk associated with these medications. The Panel felt that careful monitoring of the patient after surgery would permit restarting the medications prior to clinical flares in patients with not-severe SLE, for whom the morbidity of infection might outweigh the risk of a flare. These medications can be withheld 1 week prior to surgery, permitting some return of normal immune function, and restarted at 3–5 days after surgery in the absence of wound healing complications or infection at the surgical site or elsewhere. There are multiple mechanisms postulated for immunosuppression with these medications, including leukopenia, interference with T cell costimulatory signaling, and blocking the de novo pathway of purine synthesis, with different time courses for onset and reversal (101,102).

6. RA, SpA including AS and PsA, JIA, or SLE

Restart biologic therapy in patients for whom biologic therapy was withheld prior to undergoing THA or TKA once the wound shows evidence of healing (typically ~14 days), all sutures/staples are out, there is no significant swelling, erythema, or drainage, and there is no clinical evidence of non–surgical site infections (Table 2).

The decision to restart antirheumatic therapy can be based on evaluation of the patient's wound status and clinical judgment for absence of surgical and non–surgical site infections; wound closure is typically reached by 14 days. Therefore, biologic therapy can be restarted once the wound shows evidence of healing (typically ~14 days), all sutures/staples are out, there is no significant swelling, erythema, or drainage, and there is no clinical evidence of

Table 2. Recommendations for perioperative management of antirheumatic drug therapy in patients with rheumatic diseases undergoing elective THA or TKA*

Recommendation/strength of recommendation (bold indicates conditional)	Level of evidence
RA, SpA including AS and PsA, JIA, or SLE: Continue the current dose of methotrexate, leflunomide, hydroxychloroquine, and/or sulfasalazine (nonbiologic DMARDs) for patients undergoing elective THA or TKA. • RCTs of continuing vs. discontinuing DMARDs at the time of surgery revealed that the risk of infections was not increased, but in fact decreased, when DMARDs were continued, with an RR of 0.39 (95% CI 0.17–0.91) (37,38). Evidence indicates a low infection risk with these DMARDs in settings other than THA and TKA (39). • Disease flares after surgery occur frequently, and continuing DMARDs decreases the risk (RR 0.06 [95% CI 0.0–1.10]) (37,40), yet flares were significantly less important than infection for the Patient Panel.	Low to moderate
RA, SpA including AS and PsA, JIA, or SLE: Withhold all current biologic agents (see Figure 1) prior to surgery in patients undergoing elective THA or TKA, and plan the surgery at the end of the dosing cycle for that specific medication. • RCTs (nonsurgical) demonstrated an increase in infection risk associated with use of all biologic agents (41–87). • Avoiding infection was significantly more important to patients than flares for patients with RA and JIA. • Meta-analysis and network meta-analysis revealed that infection risk for biologic agents is strongly associated with high-dose therapy and may not be associated with low-dose biologic agents (42). • Serum half-life may not correspond to the duration of the immune-suppressant effect, so the dosing cycle was chosen as more relevant in determining the withholding interval (88–91). • Until further studies have clarified and established differences in risk between biologic agents, there was insufficient evidence to support separating biologic agent management in the perioperative period (43–89). • For SLE, there was paucity of data supporting perioperative benefit in SLE (93–95). • A systematic review of rituximab vs. placebo (and occasionally vs. control treatment including nonbiologic DMARDs) in nonsurgical patients with RA and SLE revealed the risk of all serious adverse events with a range of RRs from 0.85 (95% CI 0.62–1.17) to 0.89 (95% CI 0.7–1.14) (59,92). • Observational studies reveal that patients with SLE, particularly those with active or severe SLE, are at a higher risk for adverse events after surgery. • Belimumab is indicated for use in not-severe SLE, which is not thought to increase perioperative risk (95,96). • As an example, using this guideline, patients treated with rituximab every 6 months would schedule their surgery, when possible, at the week after the first withheld dose during month 7. Patients receiving belimumab, which is given every 4 weeks, would schedule their surgery during week 5. • Patients treated with adalimumab, dosed at 2-week intervals, would plan their surgery in week 3, while patients treated with infliximab, when dosed every 8 weeks, would schedule their surgery in the week after the first withheld dose during week 9.	Low
RA, SpA including AS and PsA, or JIA: Withhold tofacitinib for at least 7 days prior to surgery in patients undergoing THA or TKA. • Indirect evidence from systematic reviews and meta-analyses of tofacitinib vs. placebo (and occasionally vs. control treatment including nonbiologic DMARDs) in nonsurgical patients shows that the risk of serious infections was increased with tofacitinib with an incidence rate of 2.91 (95% CI 2.27–3.74) (97) and higher risk of all infections with an RR of 5.7 (95% CI 1.8–18.1) (48). • Although this drug has an extremely short serum half-life, little is known about the duration of immunosuppression after the drug is withheld. Therefore, the Panel recognized that the recommendation for the duration of withholding may change in the future, as physician and patient experience with this drug grows (41,47,48,51,77,79,97,98).	Low
Severe SLE: Continue the current dose of mycophenolate mofetil, azathioprine, cyclosporine, or tacrolimus through the surgical period in all patients undergoing THA or TKA (see Figure 1). • The Panel recognized that there is a great deal of uncertainty and little published experience regarding risks associated with perioperative medication management in patients with severe SLE. • Indirect evidence with organ transplant patients supports continuing anti-rejection therapy without interruption at the time of surgery (99,100). • Decisions regarding elective surgery in patients with severe SLE should be made on an individual basis with the patient's rheumatologist.	Low

(continued)

Table 2. *(Cont'd)*

Recommendation/strength of recommendation (bold indicates conditional)	Level of evidence
SLE (not severe): Withhold the current dose of mycophenolate mofetil, azathioprine, cyclosporine, or tacrolimus 1 week prior to surgery in all patients undergoing THA or TKA. • The time course to flares in not-severe SLE is not known. • The morbidity of prosthetic joint infection may be more severe than a flare in SLE that is not severe. • These medications can be withheld 1 week prior to surgery, permitting return of some immune function, and restarted at 3–5 days after surgery in the absence of wound healing complications or infection at the surgical site or elsewhere. • There are multiple mechanisms postulated for immunosuppression with these medications, including leukopenia, interference with T cell costimulatory signaling, and blocking the de novo pathway of purine synthesis, with different time courses for onset and reversal (101,102). • Suggest a conservative withhold of 7 days prior to surgery until additional research increases understanding of these medications.	Low
RA, SpA including AS and PsA, JIA, or SLE: Restart biologic therapy in patients for whom biologic therapy was withheld prior to undergoing THA and TKA once the wound shows evidence of healing (typically ~14 days), all sutures/staples are out, there is no significant swelling, erythema, or drainage, and there is no clinical evidence of non–surgical site infections, rather than shorter or longer periods of withholding. • The decision to restart antirheumatic therapy should be based on careful assessment of the patient's wound status and clinical judgment for absence of surgical and non–surgical site infections. Normal wound closure typically requires ~14 days.	Low
RA, SpA including AS and PsA, or SLE: Continue the current daily dose of glucocorticoids in patients who are receiving glucocorticoids for their rheumatic condition and undergoing THA or TKA, rather than administering perioperative supra-physiologic glucocorticoid doses (so-called "stress dosing"). • This recommendation specifically refers to adults with RA, AS, PsA or SLE who are receiving glucocorticoids for their rheumatic condition, and does not refer to JIA patients receiving glucocorticoids who may have received glucocorticoids during childhood developmental stages, or to patients receiving glucocorticoids to treat primary adrenal insufficiency or primary hypothalamic disease. • The literature review found information on hemodynamic instability in a systematic literature review on patients with rheumatic diseases whose mean prednisone (or equivalent) dose was ≤16 mg/day. • The CDC considers the cut-off for immunosuppression at 20 mg of prednisone/day for at least 2 weeks, and observational studies demonstrate an increase in arthroplasty infection risk with long-term steroid use >15 mg/day. • Optimization for THA and TKA should include carefully tapering the glucocorticoid dose prior to surgery to <20 mg/day, when possible (102,103).	Low

* THA = total hip arthroplasty; TKA = total knee arthroplasty; RA = rheumatoid arthritis; SpA = spondyloarthritis; AS = ankylosing spondylitis; PsA = psoriatic arthritis; JIA = juvenile idiopathic arthritis; SLE = systemic lupus erythematosus; DMARDs = disease-modifying antirheumatic drugs; RCTs = randomized controlled trials; RR = relative risk; 95% CI = 95% confidence interval; CDC = Centers for Disease Control and Prevention.

non–surgical site infections. There is no direct evidence regarding the optimal time to restart medication after surgery, but standard precautions for biologic agents warn against use in patients with an active infection or in high-risk settings, such as with an open wound.

7. RA, SpA including AS and PsA, or SLE

Continue the current daily dose of glucocorticoids in adult patients with RA, SpA including AS and PsA, or SLE who are receiving glucocorticoids for their rheumatic condition and undergoing THA or TKA, rather than administering perioperative supra-physiologic glucocorticoid doses (so-called "stress dosing") (Table 2).

Hemodynamic instability/hypotension and infection risk were 2 specific areas of concern with regard to perioperative glucocorticoid dosing. Regarding hemodynamic instability, the recommendation to continue the current daily dose of glucocorticoids in adult patients who are receiving glucocorticoids, rather than administering perioperative supra-physiologic glucocorticoid doses ("stress dosing"), specifically refers to adults with RA, AS, PsA, or SLE who are receiving glucocorticoids (≤16 mg/day prednisone or equivalent) for their rheumatic condition; it does not refer to JIA patients receiving glucocorticoids who may have been treated with glucocorticoids during childhood developmental stages, or to patients receiving glucocorticoids to treat primary adrenal insufficiency or primary hypothalamic disease. Low-quality RCT evidence (rated down for indirectness due to varying glucocorticoid doses, heterogeneity of surgical procedures, and imprecision due to small numbers) and evidence from observational trials summarized in a systematic review suggested that there was no significant hemodynamic difference between those patients given their current daily glucocorticoid dose compared to those receiving "stress-dose steroids" (103).

Regarding the infection risk, the Panel noted that the cutoff for immunosuppression according to the Centers for Disease Control and Prevention was 20 mg/day of prednisone for at least 2 weeks, in the context of risk

associated with the administration of live vaccines. In addition, observational studies demonstrate an increase in infection risk following TJA for long-term users of glucocorticoids at doses of >15 mg/day. A patient in optimal condition for elective THA or TKA would be receiving a dose of prednisone or equivalent that was <20 mg/day, when possible, and receive their usual daily dose rather than the "stress dose" in light of the effect on infection risk (102,103).

DISCUSSION

The 2017 ACR/AAHKS guideline for the perioperative management of antirheumatic drug therapy for adults undergoing elective THA and TKA was designed for use by clinicians and patients during the perioperative period. Included recommendations address the use of treatment with antirheumatic drugs (including DMARDs, tofacitinib, biologic agents, and glucocorticoids) for the adult patient with RA, SpA including AS and PsA, JIA, or SLE, recognizing that antirheumatic medication is frequently used at the time of THA or TKA, and that rates of infection and adverse events, including readmission, are increased in this population. The optimal management of antirheumatic medications to treat these diseases may mitigate risks. We have used GRADE methodology to synthesize the best available evidence and have been transparent regarding both the strength of the recommendation and the limited quality of the evidence for each recommendation.

This project brought together major stakeholders (orthopedic arthroplasty surgeons, rheumatologists, methodologists, and patients) to create a patient-centric, expert-led group to determine optimal management of these high-risk patients through a group consensus process. To date, there has been little to no consensus among orthopedic surgeons or rheumatologists on the optimal way to manage antirheumatic medications during the TJA perioperative period, which often leads to uncertainty in decision-making for physicians and patients alike.

A major limitation of this guideline is the paucity of high-quality, direct evidence regarding medications and perioperative risk of infection and flare. The indirect nature of the evidence was the primary reason the quality of evidence was considered low, which led to a conditional designation for all the recommendations. Nonetheless, because patients with rheumatic diseases frequently undergo THA and TKA while receiving DMARDs and biologic agents, we sought to fulfill the need for guidance based on the best available evidence and agreement among stakeholders. The Patient Panel thought infection risk was much more important than flare risk, and this drove the direction of the recommendations (uniformly in favor of withholding any medications in which evidence from nonoperative populations suggested an increase in infection).

Topics such as cardiac risk, deep venous thrombosis risk, risk of 90-day readmissions, and management and care of the cervical spine are related to the perioperative care of patients with rheumatic disease who are undergoing THA or TKA. The guideline was limited, however, to risks attributable to perioperative management of antirheumatic drug therapy.

Antirheumatic medications and disease states were initially evaluated individually. Due to a lack of evidence, however, for each individual medication and disease state, the medications were combined by category and diseases, with the exception of SLE.

With regard to patients with SLE, the Panel recognized that recommendations for perioperative medication management in a complex disease such as SLE would be challenging, as SLE is frequently complicated by multiple organ involvement, as well as complex or unusual medication regimens. Moreover, SLE flares may be organ-threatening, and SLE patients may be more averse to risk of flare than to infection; therefore, the lack of SLE patients on the Patient Panel was a limitation. Nonetheless, the orthopedic and rheumatology stakeholders felt strongly that perioperative medication management guidance was needed for SLE patients.

The recommendation to restart biologic agents was based on the patient's wound healing (generally requiring a minimum of 14 days) and clinical judgment for the absence of both surgical site and non–surgical site infection. While there are differences in practice patterns and many patients do not return to their surgeon within 2 weeks of discharge, screening mechanisms to assess the wound, including utilizing visiting nurse services, and taking photographs of the wound for review by e-mail, smartphone, or other mobile health technologies, would help to identify those who should be evaluated in person prior to restarting biologic agents.

The Voting Panel thought it worthwhile to suggest a research roadmap for future studies that could be conducted as part of a collaboration between the 2 organizations. The team discussed the following topics and recommended that they be targeted for future research: 1) Perioperative glucocorticoid management. While the RCT data support continuing the current glucocorticoid dose rather than "stress dosing," limited numbers of patients and heterogeneity of dose, diagnosis, and surgical procedure leave us with only low-quality evidence; 2) Perioperative management of biologic agents. The Voting Panel suggested investigating existing biologic agents through registries and administrative databases, as well as planning multicenter RCTs to define the optimal medication management strategy; and 3) Perioperative management of DMARDs. Currently, data from RCTs for patients undergoing surgery reflect older, lower-dose regimens for methotrexate, and studies of leflunomide include small numbers of patients. Multicenter RCTs should be performed to determine the optimal perioperative management regimens and include assessment of comorbidities and glucocorticoid use in the study design.

The recommendations that form this guideline are not treatment mandates, but can be used to provide guidance and promote discussion regarding medication management prior to surgery. The authors recognize that not all potential perioperative clinical scenarios are covered by this guideline, but the most common clinical scenarios are addressed. This guideline does not replace perioperative clinical assessment and optimization, and does not

preclude a discussion of the risks and benefits of surgery as patients and their physicians prepare for THA and TKA.

In summary, this guideline provides clinicians and patients with a working document regarding how to manage antirheumatic drugs in the time leading up to elective THA and TKA. The recommendations provide important guidance that was informed by the available literature, clinical expertise and experience, and patient values and preferences. The acknowledgment of low-quality evidence in this area should lay the foundation for future research.

ACKNOWLEDGMENTS

The authors thank Anne Bass, MD, Elie Berbari, MD, Mark Figgie, MD, MBA, Stuart Goodman, MD, PhD, Marc Hochberg, MD, MPH, Eric Matteson, MD, and William Benjamin Nowell, PhD, MSW for serving on the Expert Panel. The authors also thank the Arthritis Foundation and the Global Healthy Living Foundation for their assistance with patient involvement in this guideline project, as well as the patients who participated on the Patient Panel (Katie Acompora, Deserae Constantineau, Marshall Davis, Laureen Fable, Nancy Franklin-Hicks, Jennifer Kangal, Marna McDermott, Tiffany Ann Ohlin, Jodi Pound, Kirsten Smith, and Kelly Voight). We thank the ACR staff, including Ms Regina Parker for assistance in organizing the face-to-face meeting and coordinating the administrative aspects of the project, and Ms Robin Lane for assistance in manuscript preparation. We thank Ms Janet Waters for help in developing the literature search strategy and performing the literature search and updates, and Ms Janet Joyce for reviewing the literature search strategy.

2022 American College of Rheumatology/American Association of Hip and Knee Surgeons Guideline for the Perioperative Management of Antirheumatic Medication in Patients with Rheumatic Diseases Undergoing Elective Total Hip or Total Knee Arthroplasty

Guideline Summary

Revised July 18, 2022

This updated guideline includes changes in the recommendations regarding rituximab and belimumab for patients with severe SLE, and now includes anifrolumab and voclosporin. For patients with spondyloarthritis, recommendations have been added on management of ixekizumab and guselkumab. The recommendations have changed for management of JAK inhibitors and suggest withholding for 3 days before surgery; tofacitinib, upadicitinib, and baricitinib are now included.

This updated guideline addresses the perioperative management of disease modifying medications for adults with rheumatic diseases, specifically inflammatory arthritis (IA) and systemic lupus erythematosus (SLE) undergoing elective total hip arthroplasty (THA) and total knee arthroplasty (TKA). A panel of rheumatologists, orthopaedic surgeons, and infectious disease specialists updated the systematic literature review and included currently available medications for the clinically relevant population, intervention, comparator, and outcomes (PICO) questions, updating the 2017 recommendations*. As patients with IA and SLE are at increased risk of infection after THA and TKA, these recommendations aim to balance the risk of perioperative infection and the risk of disease flares, recognizing that all flares have an impact on quality of life but a flare in a patient with severe SLE at risk for organ damage warrants unique considerations. This updated guideline includes recently introduced immunosuppressive medications to help decision-making by clinicians and patients regarding perioperative disease modifying medication management for patients with IA and SLE at the time of elective THA or TKA.

MEDICATIONS TO CONTINUE THROUGH SURGERY		
DMARDs: CONTINUE these medications through surgery. (All patients)	**Dosing Interval**	**Recommended timing of surgery since last medication dose**
Methotrexate	Weekly	Anytime
Sulfasalazine	Once or twice daily	Anytime
Hydroxychloroquine	Once or twice daily	Anytime
Leflunomide (Arava)	Daily	Anytime
Doxycycline	Daily	Anytime
Apremilast (Otezla)	***Twice daily***	***Anytime***
SEVERE SLE-SPECIFIC MEDICATIONS††: CONTINUE these medications in the perioperative period in consultation with the treating rheumatologist.	**Dosing Interval**	**Recommended timing of surgery since last medication dose**
Mycophenolate mofetil	Twice daily	Anytime
Azathioprine	Daily or twice daily	Anytime
Cyclosporine	Twice daily	Anytime
Tacrolimus	Twice daily (IV and PO)	Anytime
Rituximab (Rituxan)	***IV Every 4-6 months***	***Month 4-6***
Belimumab (Benlysta)	***Weekly SQ***	***Anytime***
Belimumab (Benlysta)	***Monthly IV***	***Week 4***
Anifrolumab (Saphnelo)†	***IV Every 4 weeks***	***Week 4***
Voclosporin (Lupkynis)†	***Twice daily***	***Continue***

MEDICATIONS TO WITHHOLD PRIOR TO SURGERY***		
BIOLOGICS: WITHHOLD these medications through surgery		**Recommended timing of surgery since last medication dose**
Infliximab (Remicade)	Every 4, 6, or 8 weeks	Week 5, 7, or 9
Adalimumab (Humira)	Every 2 weeks	Week 3
Etanercept (Enbrel)	Every week	Week 2
Golimumab (Simponi)	Every 4 weeks (SQ) or every 8 weeks (IV)	Week 5 Week 9
Abatacept (Orencia)	Monthly (IV) or weekly (SQ)	Week 5 Week 2
Certolizumab (Cimzia)	Every 2 or 4 weeks	Week 3 or 5
Rituximab (Rituxan)	2 doses 2 weeks apart every 4-6 months	Month 7
Tocilizumab (Actemra)	Every week (SQ) or every 4 weeks (IV)	Week 2 Week 5
Anakinra (Kineret)	Daily	Day 2
IL-17-Secukinumab (Cosentyx)	Every 4 weeks	Week 5
Ustekinumab (Stelara)	Every 12 weeks	Week 13
Ixekizumab (Taltz)†	***Every 4 weeks***	***Week 5***
IL-23 Guselkumab (Tremfya)†	***Every 8 weeks***	***Week 9***
JAK inhibitors WITHHOLD this medication 3 days prior to surgery*		
Tofacitinib (Xeljanz):	***Daily or twice daily***	***Day 4***
Baricitinib (Olumiant)†	***Daily***	***Day 4***
Upadacitinib (Rinvoq)†	***Daily***	***Day 4***
NOT-SEVERE SLE: WITHHOLD these medications 1 week prior to surgery	**Dosing Interval**	**1 week after last dose**
Mycophenolate mofetil	Twice daily	**1 week after last dose**
Azathioprine	Daily or twice daily	1 week after last dose
Cyclosporine	Twice daily	**1 week after last dose**
Tacrolimus	Twice daily (IV and PO)	**1 week after last dose**
Rituximab (Rituxan)	Every 4-6 months	Month 7
Belimumab IV (Benlysta)	***Monthly***	***Week 5***
Belimumab SQ (Benlysta)	***Weekly***	***Week 2***

Dosing intervals obtained from prescribing information provided online by pharmaceutical companies.

DMARDs = disease-modifying antirheumatic drugs; SQ = subcutaneous; IV = intravenous; SLE = systemic lupus erythematosus; PO = oral.

*2017 American College of Rheumatology/American Association of Hip and Knee Surgeons Guideline for the Perioperative Management of Anti-rheumatic Medication in Patients with Rheumatic Diseases Undergoing Elective Total Hip or Total Knee Arthroplasty

Shading with Bold italics indicates recommendation that has changed since 2017.

† Drug added for 2022 update.

†† Severe SLE indicates organ threatening disease.

** Recommendation pertains to infection risk and does not account for risk of cardiac events or venous thromboembolism.

***For patients with RA, AS, PsA, or all SLE for whom anti-rheumatic therapy was held prior to undergoing TJA, restarting the anti-rheumatic therapy once the wound shows evidence of healing, any sutures/staples are out, there is no significant swelling, erythema or drainage, and there is no ongoing non-surgical site infection, which is typically about 14 days.

*This summary was approved by the ACR Board of Directors on February 24, 2022. These recommendations are included in a full manuscript, which was published in Arthritis Care and Research and Arthritis & Rheumatology June 19, 2022.**

2022 American College of Rheumatology Guideline for the Prevention and Treatment of Glucocorticoid-Induced Osteoporosis

Guideline Summary

A panel of adult and pediatric rheumatologists and endocrinologists updated the systematic literature review and included currently available medications for the prevention and treatment of glucocorticoid (GC)-induced osteoporosis. A patient panel was included in this update.

Similar to the 2017 guideline, we recommend risk stratifying patients as being at low, moderate, or high risk of fracture (Adults ≥ 40 years, FRAX® 10-year probability of major osteoporotic fracture < 10 %,10-19%, or ≥ 20% respectively). These cut points were used to stratify PICO questions and weigh potential benefits versus harms, when considering osteoporosis (OP) therapy. For all adults initiating or continuing GC therapy ≥ 2.5mg/day for > 3 months, who have never had fracture risk assessment or been treated with OP therapy, initial clinical fracture risk assessment is strongly recommended over no assessment. Clinical fracture risk factor assessment includes the dose, duration, and pattern of GC use, alcohol use, smoking history, hypogonadism, history of prior fractures, low body weight, significant weight loss, parental history of hip fracture, fall history, thyroid disease, hyperparathyroidism, rheumatoid arthritis, malabsorption, chronic liver disease, inflammatory bowel disease, and height loss. If available, BMD testing is recommended within 6 months of starting GC therapy for adults and every 1-2 years thereafter while continuing GC therapy.

A strong recommendation was made to use oral bisphosphonates (BPs) for adults ≥ 40 years receiving long-term GCs, at high risk for fracture, based on available fracture data in GIOP populations. Other agents including intravenous BPs, PTH/PTHrP, and denosumab (DEN) are also options and are conditionally recommended given lack of fracture prevention data in GIOP populations. The selection between oral and IV BP, PTH/PTHrP, and DEN should be based on patient and physician preferences. Selective estrogen receptor modulators (SERMs) and romosozumab (ROM) may be used in selected patients, after careful consideration of potential harms including thrombosis, stroke, and cardiovascular events.

Table 1: Definitions of selected terms used in the recommendations and upgraded position statements for GIOP

Term	Adults ≥ 40 years of age	Adults < 40 years of age
Major osteoporotic fracture (MOF)	Non-traumatic or pathological fractures of the spine, hip, wrist, or humerus	Non-traumatic or pathological fractures of the spine, hip, wrist, or humerus
Clinical fracture risk assessment	History of GC use, evaluation for falls, fractures, frailty, secondary causes of osteoporosis, FRAX® with GC adjustment, BMD testing	History of GC use, evaluation for falls, fractures, frailty, secondary causes of osteoporosis, BMD testing (FRAX® not validated at age <40 years)

Follow up risk assessment during GC treatment	FRAX® and BMD testing every 1-2 years for untreated patients; BMD testing every 1-2 years for OP-treated patients, whether receiving or completed OP therapy	BMD testing every 1-2 years
FRAX® GC correction	If GC dose is > 7.5 mg/day, multiply the 10-year risk of major osteoporotic fracture by 1.15 and the hip fracture risk by 1.2 *	Not applicable
Fracture risk categories in patients not yet receiving OP treatment		
High	Prior OP fracture (s) **OR** Hip or spine BMD T ≤ -2.5 **OR** FRAX® (GC-Adjusted) 10-year risk of MOF ≥ 20%, hip ≥ 3% **OR** GC ≥ 30mg/day or cumulative GC doses ≥ 5 grams/year	Prior OP fracture (s) **OR** GC ≥ 30mg/day **OR** cumulative GC doses ≥ 5 grams/year
Moderate	FRAX® (GC-Adjusted) 10-year risk of MOF ≥ 10 and < 20%, hip > 1 and < 3%	Continuing GC treatment ≥ 7.5mg/day for ≥ 6 months **AND** (Hip or spine BMD Z score < -3) **OR** (rapid bone loss ≥ 10% at the hip or spine over 1-2 years)
Low	FRAX® (GC-Adjusted) 10-year risk of MOF < 10%, hip ≤ 1%	None of the above risk factors other than GC treatment
Treatments	***Recommended pharmacological treatment strategy***	
Calcium and Vitamin D	In addition to lifestyle modifications, optimized intake of dietary and supplemental calcium and vitamin D based on age-appropriate U.S. Recommended Dietary Allowances.	
Bisphosphonates (BP) Alendronate (oral) Risedronate (oral) Ibandronate (oral/ IV) Zoledronic acid (IV) **PTH & PTHrP Agonists** Teriparatide (TER) Abaloparatide (ABL) **Anti-RANKL** Denosumab (DEN) **SERM** Raloxifene (RAL) Bazedoxifene (BAZ) **Anti-sclerostin** Romosozumab (ROM)	*First line:* *Strong recommendation based on fracture data in GIOP:* Oral BP *Conditional recommendation due to lack of fracture data in GIOP:* IV BP[$], DEN, PTH/PTHrP Conditionally *recommended against due to CVD and thrombosis risk unless first-line therapies are contraindicated or not tolerated: ROM, SERM*	*First line:* *Conditional recommendation* Oral or IV BP[$], PTH/PTHrP or DEN Conditionally *recommended against due to CVD and thrombosis risk unless first-line therapies are contraindicated or not tolerated:* SERM and ROM

BP = bisphosphonate; PTH = parathyroid hormone; PTHrP = PTH-related protein; RANKL = Receptor activator of NF-κβ-Ligand; SERM = Selective estrogen receptor modulator; BMD = bone mineral density; GC= glucocorticoid; FRAX® = https//www.shef.ac.uk/FRAX/Tool.jsp; MOF = major osteoporotic fracture; * FRAX® GC correction example: if hip fracture risk is 2.0% multiply by 1.2 for adjusted risk =2.4%; [$] = IV BP not preferred in women of child-bearing potential

Osteoporosis Medications for Patients with Chronic Kidney Disease or Following Renal Transplant

Bisphosphonates should generally not be used in patients with an eGFR < 35 ml/min. When eGFR is < 35 ml/min, the risk of renal osteodystrophy, including adynamic bone disease, osteomalacia, osteitis fibrosa cystica and mixed uremic osteodystrophy, is increased. As such, metabolic bone disease expert evaluation for chronic kidney disease-mineral and bone disorder (CKD-MBD) is conditionally recommended to exclude these conditions. Once excluded, no dose adjustment is needed when prescribing DEN, PTH/PTHrP, or romosozumab (ROM).

Table 2. Recommendations for initial treatment for prevention of GIOP in adults beginning long-term GC therapy

Recommendations for patients taking prednisone ≥ 2.5mg/day for > 3months	Certainty of evidence	PICO evidence report basis	Page no(s). of evidence tables
For adults and children beginning or continuing chronic GC treatment at low, moderate, or high risk of fracture, optimizing dietary and supplemental calcium and vitamin D in addition to lifestyle modifications (CAL/VIT D/LM) is **conditionally** recommended. All additional recommendations are in addition to CAL/VIT D/LM).	Low or Very Low	1.1a,b,c-1.3a,b,c, 2.1-2.3, 7.16-7.26	6-8, 47-48, 63-65, 141-144,148-151
In adults ≥ 40 years			
With ***LOW*** fracture risk, adding any OP medications to CAL/VIT D /LM based on known harms with no evidence of benefit is **strongly** recommended ***against***.	Very Low	1.4a-1.28a	8-46
With ***MODERATE*** fracture risk, oral or IV BP, PTH/PTHrP, or DEN over no OP therapy is **conditionally** recommended.	Moderate to Very Low	1.4b-1.28b	42-47
With ***MODERATE*** fracture risk, using ROM or SERM is **conditionally** recommended *against* except for in patients intolerant of other agents, due to risk of life-threatening harms.	Very Low	1.12b, 1.16b,1.17b,1.21b-1.25b, 1.28b	40-41, 44-47
With ***HIGH*** fracture risk, oral BP over not giving OP therapy is **strongly** recommended[#]. IV BP, PTH/PTHrP, or DEN over no OP therapy is **conditionally** recommended[$].	Low or Very Low	1.5c-1.28c	48-53
With ***HIGH*** fracture risk, using ROM or SERM is **conditionally** recommended ***against*** except for patients intolerant of other agents due to risk of life- threatening harms	Very Low	1.16c, 1.21c, 1.28c	50, 52-53

With ***HIGH*** fracture risk, using two different OP medications at the same time is **conditionally** recommended ***against***.	Very Low	1.29-1.35	53-62
For *post-menopausal* women at moderate or ***HIGH*** fracture risk, SERM is **conditionally** recommended ***against*** except for in patients intolerant of other agents, due to risk of life- threatening harms.	Very Low	1.12b,c, 1.17b,c 1.22b,c-1.25b,c	43-46, 50-52
Adults ≥ 40 years receiving high-dose GC (initial dose ≥ 30 mg/day or cumulative dose ≥ 5 gm in 1 year)			
Treating with oral or IV BP, PTH/PTHrP, DEN, SERM, or ROM is **conditionally** recommended.	Low	6.4a-6.19a	120-130
In adults <40 years			
With ***LOW*** fracture risk, adding OP medications over CAL/VIT D/ LM alone is **strongly** recommended ***against*** due to known risk of harms and no evidence of benefit.	Very Low	4.4a-4.13a	91-101
With ***MODERATE or HIGH*** fracture risk, oral or IV BP[%], DEN, or PTH/PTHrP therapy is **conditionally** recommended.	Low or Very Low	2.4-2.22, 3.4-3.17	65-76, 79-84.
With ***MODERATE or HIGH*** fracture risk, using ROM is **conditionally** recommended ***against*** due to risk of life-threatening harms.	Very Low	2.9, 3.9	70, 86
Adults < 40 years[#] receiving high-dose GC (initial dose ≥ 30 mg/day > 30 days or cumulative dose ≥ 5 gm in 1 year)			
Treating with oral or IV BP[%], PTH/PTHrP or DEN is **conditionally** recommended over SERM or ROM due to risk of life-threatening harms	Low	6.1b-6.19b	133-141
For adults with solid organ transplants, glomerular filtration rate ≥ 35 ml/minute, and no evidence of chronic kidney disease-mineral and bone disorder (CKD-MBD)*			
Expert evaluation for CKD-MBD in renal transplant recipients is **conditionally** recommended.	Low	5.1-5.26	103-118
Personalized treatment with oral or IV BP, DEN, PTH/PTHrP, or SERM based on individual patient factors is **conditionally** recommended.	Low	5.1-5.26	103-118
Using ROM due to CVD risk and lack of safety in this population is **conditionally** recommended ***against***.	Very Low	5.9	112
Children ages 4-17 years treated with GCs at any dose for > 3 months (Low or moderate risk)			
Optimization of dietary and supplementation of CAL and VIT D is **conditionally** recommended as recommended by U.S. RDA depending on the age of the child.	Very Low	7.1a-7.4a	141-144
Starting oral or IV BP is **conditionally** recommended ***against*** due to low risk of OP fractures in this age group.	Very Low	7.5a	144

Children ages 4-17 years with *an osteoporotic fracture* who are continuing treatment with GCs at a dose of ≥ 0.1 mg/kg/day for > 3 months (high risk)			
Treating with an oral or IV BP is **conditionally** recommended.	Very Low	7.1b-7.2b	147-253

GIOP = Glucocorticoid-induced osteoporosis, BMD = Bone mineral density, GC = glucocorticoids, BP = bisphosphonate, IV = intravenous, DEN = denosumab, PTH/PTHrP = parathyroid hormone/ parathyroid hormone related protein, RAL = raloxifene, ROM = romosozumab, OP = osteoporosis; PICO = Patients, intervention, comparison, outcome; CAL/VIT D/LM = calcium/ vitamin D/ lifestyle modifications; # strong recommendation based on fracture data, $ conditional due to lack of fracture data, % who are not planning on pregnancy during the OP treatment period or are using effective birth control if sexually active; CAL = calcium; CVD = cardiovascular disease; SERM = selective estrogen receptor modulator; U.S. RDA = United States Recommended Dietary Allowances; CKD-MBD = chronic kidney disease-mineral and bone disorder; *includes osteomalacia, adynamic bone disease, osteitis fibrosa cystica, mixed uremic osteodystrophy

This updated guideline includes recommendations on abaloparatide (PTHrP) and romosozumab (ROM), which are newly available since the 2017 guideline. It also addresses sequential therapy, which was not addressed in the past. Patients should know that osteoporosis therapy with denosumab (DEN), teriparatide (PTH), PTHrP, or ROM will need sequential osteoporosis therapy to prevent rapid bone loss after these drugs are discontinued. Recommendations for sequential therapies are based in part on initial study designs, long term follow-up studies, and new clinical trials. Patients completing a course of DEN should transition to 1-2 years of a BP. Patients completing a course of PTH, PTHrP, or ROM need to transition to a BP or DEN. Discontinuation of DEN after two or more doses has been associated with rapid bone loss and development of new vertebral compression fractures as soon as 7-9 months after the last dose. As such, BP therapy is recommended beginning at 6-7 months after the last dose of DEN. The precise timing, dose and duration of BP use after DEN cessation is under study, but treatment for a least 1 year seems prudent, until additional research is available. Stopping PTH/PTHrP without transition to another therapy can also result in rapid bone loss and new fractures, which can be prevented by institution of oral or IV BP or DEN. Stopping ROM without transition to another therapy can result in bone loss, which can be prevented by the institution of oral or IV BP or DEN.

Sequential Treatments Recommended When Initial OP Therapy and GC are Discontinued and at Low or Moderate Risk

Initial OP therapy	**Subsequent OP therapy options**
Oral/IV Bisphosphonate	No subsequent OP therapy needed
SERM	No subsequent OP therapy needed
PTH/PTHrP	Oral or IV Bisphosphonate, **OR** Denosumab followed by Bisphosphonate
Denosumab	Oral or IV Bisphosphonate
Romosozumab	Oral or IV Bisphosphonate, **OR** Denosumab followed by Bisphosphonate

Sequential Treatments Recommended When Initial OP Therapy and GC are Discontinued and Patient Remains High Risk

Continue current therapy or switch to IV Bisphosphonate, DEN, PTH/PTHrP, SERM or romosozumab

This summary was initially approved by the ACR Board of Directors on August 13, 2022 and updated on November 9, 2022. These recommendations are included in a full manuscript, which will be submitted for publication in Arthritis & Rheumatology and Arthritis Care and Research.

Objective. **To develop recommendations for prevention and treatment of glucocorticoid-induced osteoporosis (GIOP).**

Methods. **We conducted a systematic review to synthesize the evidence for the benefits and harms of GIOP prevention and treatment options. The Grading of Recommendations Assessment, Development and Evaluation methodology was used to rate the quality of evidence. We used a group consensus process to determine the final recommendations and grade their strength. The guideline addresses initial assessment and reassessment in patients beginning or continuing long-term (≥3 months) glucocorticoid (GC) treatment, as well as the relative benefits and harms of lifestyle modification and of calcium, vitamin D, bisphosphonate, raloxifene, teriparatide, and denosumab treatment in the general adult population receiving long-term GC treatment, as well as in special populations of long-term GC users.**

Results. **Because of limited evidence regarding the benefits and harms of interventions in GC users, most recommendations in this guideline are conditional (uncertain balance between benefits and harms). Recommendations include treating only with calcium and vitamin D in adults at low fracture risk, treating with calcium and vitamin D plus an additional osteoporosis medication (oral bisphosphonate preferred) in adults at moderate-to-high fracture risk, continuing calcium plus vitamin D but switching from an oral bisphosphonate to another antifracture medication in adults in whom oral bisphosphonate treatment is not appropriate, and continuing oral bisphosphonate treatment or switching to another antifracture medication in adults who complete a planned oral bisphosphonate regimen but continue to receive GC treatment. Recommendations for special populations, including children, people with organ transplants, women of childbearing potential, and people receiving very high-dose GC treatment, are also made.**

Conclusion. **This guideline provides direction for clinicians and patients making treatment decisions. Clinicians and patients should use a shared decision-making process that accounts for patients' values, preferences, and comorbidities. These recommendations should not be used to limit or deny access to therapies.**

INTRODUCTION

Glucocorticoids (GCs) play an important role in the treatment of many inflammatory conditions. It is estimated that 1% of the US population is treated long-term with GCs (1). However, GC use causes significant toxicity, including bone loss and fractures (2,3). More than 10% of patients who receive long-term GC treatment are diagnosed with a fracture, and 30–40% have radiographic evidence of vertebral fractures (4,5). The highest rate of bone loss occurs within the first 3–6 months of GC treatment, and a slower decline continues with persistent use (6). Both high daily and high cumulative GC doses increase risk of fracture, particularly vertebral fracture, due to the greater effects of GCs on trabecular bone than on cortical bone. Risk factors for GC-induced fracture include low bone strength at the beginning of GC treatment and the rate of decline in bone mass during treatment, which is largely determined by the dose and duration of GC use. In children, GC treatment also affects bone strength, growth, and total adult skeletal mass, with a similar profile of risk factors (7–10).

However, GC treatment is a potentially reversible risk factor for glucocorticoid-induced osteoporosis (GIOP); if GC treatment is terminated, bone mineral density (BMD) increases and fracture risk declines (6,11,12). In addition, the absolute risk of future fracture in an individual is substantially influenced by demographic and other characteristics (age, race, sex, and concomitant OP risk factors). For these reasons, it is important to identify those patients taking GCs for whom the benefits of preventive therapy sufficiently outweigh potential harms.

Numerous risk calculators can be applied in clinical practice to provide estimates of risk of major OP fracture and hip fracture clinically diagnosed, with adjustment for GC dose in some but not all calculators (13–15). Most stratify GC use into 2 categories: low (prednisone ≤7.5 mg/day) or high (>7.5 mg/day), based on data from clinical trials and epidemiologic studies (15,16) demonstrating increasing fracture risk with higher daily doses. However, these calculators may underestimate the fracture risk in patients with prolonged treatment with very high doses of GCs for conditions such as giant cell arteritis, vasculitis, lupus, and dermatomyositis (16,17). Van Staa et al reported a marked increase in relative risk of vertebral and hip fractures in patients who had received treatment with prednisolone ≥30 mg/day with a cumulative dose of >5 gm (15).

There are insufficient data to develop individual prediction tools for children and for adults <40 years of age. Nevertheless, observational data indicate a substantial risk of clinically diagnosed vertebral fracture among premenopausal women ≥30 years of age receiving very high doses of GCs (10-year risk 5–20%) (18–25).

Despite increasing information about risk factors for fracture in GC users and the availability of effective therapies to prevent fracture, many long-term GC users never receive therapy to prevent bone loss or are treated

only after a fracture has occurred (26,27). The American College of Rheumatology (ACR) identified GIOP as an important public health issue and first published recommendations for its prevention and treatment in 1996 (28). The ACR updated these guidelines in 2001 and 2010, as new techniques for assessing fracture risk and new information about risk factors and therapies became available (28–30). The present ACR guideline outlines the treatment recommendations for GIOP. The guideline was developed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach (see below) and included therapies for the treatment of OP approved by the US Food and Drug Administration before 2015. No other therapies have been approved as of the time of publication of these guidelines.

METHODS

Methodology overview. We developed this guideline according to the ACR guideline development process (http://www.rheumatology.org/Practice-Quality/Clinical-Support/Clinical-Practice-Guidelines). This process includes the GRADE methodology (www.gradeworkinggroup.org) (31–33). Conflicts of interest and disclosures were determined and managed according to ACR policy (https://www.rheumatology.org/Portals/0/Files/GIOP-Guidelines-Disclosure-Summary.pdf). The full methods are described in detail in Supplementary Appendix 1 (available on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract). This work involved 4 teams: 1) a Core Leadership Team (4 members), which supervised and coordinated the project and drafted the clinical questions and manuscript; 2) a Literature Review Team, which completed the literature search and abstraction; 3) an Expert Panel, which developed the clinical questions (PICO [population/intervention/comparator/outcomes] questions) and the scope of the guideline project; and 4) a Voting Panel, which included adult and pediatric rheumatologists, internists, a nephrologist, a pulmonologist, a gastroenterologist, medical specialists with clinical expertise in treating GIOP, and a patient who provided input from the patient perspective and voted on the recommendations. Rosters of the team and panel members are shown in Supplementary Appendix 2 (http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract).

Framework for the GIOP guideline development. The Panel ranked fracture (hip, vertebral, nonvertebral) as the *critically important outcome measure* for treatment evaluation. *Important outcome measures* included adverse effects of treatments, in particular the incidence of serious and total adverse events (see Supplementary Appendix 3 [http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract] for a list of adverse events).

At the initial meeting, the Voting Panel and Expert Panel agreed that the scope of the project should be the assessment, prevention, and treatment of OP and fractures in children and adults taking glucocorticoids (prednisone at >2.5 mg/day for ≥3 months), including patients with organ transplants, women of childbearing potential, and people receiving very high-dose GCs. Treatment of people using inhaled GCs and those with a glomerular filtration rate of <30 ml/minute were not addressed in these guidelines.

Adult men and women were divided into 2 groups based on age (≥40 years or <40 years). After population risk groups were defined, interventions and comparators for each clinical scenario were specified using a PICO question (see list of PICO questions in Supplementary Appendix 3). PICO questions included assessment and reassessment of fracture risks, treatment comparisons, and questions about duration and reassessment of treatment. When it was necessary to use BMD to support a recommendation (which was the case in only 4 PICO questions, all addressing pediatric patients with GIOP), the Voting Panel downgraded the quality of evidence for indirectness, since BMD provides only indirect evidence of the impact on fracture.

Systematic synthesis of the literature. We performed systematic searches of the published English-language literature including OVID Medline, PubMed, Embase, and the Cochrane Library (including Cochrane Database of Systematic Reviews, Database of Abstracts of Reviews of Effects, Cochrane Central Register of Controlled Trials, and Health Technology Assessments) from the beginning of each database through October 6, 2015 (Supplementary Appendix 4, on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract), and update searches were conducted on April 23, 2016. We performed duplicate screening of literature search results using DistillerSR software (https://distillercer.com/products/distillersr-systematic-review-software/) (Supplementary Appendix 5, http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract). Data were extracted into RevMan software (http://tech.cochrane.org/revman), and the quality of each study was evaluated using the Cochrane risk of bias tool (http://handbook.cochrane.org/). We exported RevMan files into GRADEpro software to formulate a GRADE summary of findings table (Supplementary Appendix 3) for each PICO question (34). The overall quality of evidence was evaluated using GRADE quality assessment criteria (31).

In clinical scenarios not addressed by data from randomized clinical trials, data from observational cohort studies were used to estimate relative effects. In situations in which the question had not been tested in a sample of patients taking GCs but had been tested in a non-GIOP population, we applied the relative risk values from that study, making the assumption that the effect was generalizable, but we downgraded the quality of evidence for indirectness.

We projected absolute risk reduction within each risk stratum according to hypothetical baseline fracture risk ranging from 1% to 20%. The following cut points were used to stratify levels of risk: <5% incidence of vertebral fractures over 5 years, between 5% and <10%, and ≥10%. The Voting Panel then made recommendations based on absolute fracture reduction with treatment in each of these strata. We focused on vertebral fracture rates because this outcome was more consistently reported in the literature and because of the greater effects of GCs on trabecular bone.

Moving from evidence to recommendations. GRADE methodology specifies that panels make recommendations based on the balance of relative benefits and harms of the treatment options under consideration, the quality of the evidence (i.e., confidence in the effect estimates), and patients' values and preferences. Key to the recommendation is the

Table 1. Fracture risk categories in GC-treated patients

	Adults ≥40 years of age	Adults <40 years of age
High fracture risk	Prior osteoporotic fracture(s) Hip or spine bone mineral density T score ≤−2.5 in men age ≥50 years and postmenopausal women FRAX* (GC-adjusted†) 10-year risk of major osteoporotic fracture‡ ≥20% FRAX* (GC-adjusted†) 10-year risk of hip fracture ≥3%	Prior osteoporotic fracture(s)
Moderate fracture risk	FRAX* (GC-adjusted†) 10-year risk of major osteoporotic fracture‡ 10–19% FRAX* (GC-adjusted†) 10-year risk of hip fracture >1% and <3%	Hip or spine bone mineral density Z score <−3 **or** rapid bone loss (≥10% at the hip or spine over 1 year) **and** Continuing GC treatment at ≥7.5 mg/day for ≥6 months
Low fracture risk	FRAX* (GC-adjusted†) 10-year risk of major osteoporotic fracture‡ <10% FRAX* (GC-adjusted†) 10-year risk of hip fracture ≤1%	None of above risk factors other than GC treatment

* https//www.shef.ac.uk/FRAX/tool.jsp.
† Increase the risk generated with FRAX by 1.15 for major osteoporotic fracture and 1.2 for hip fracture if glucocorticoid (GC) treatment is >7.5 mg/day (e.g., if hip fracture risk is 2.0%, increase to 2.4%).
‡ Major osteoporotic fracture includes fractures of the spine (clinical), hip, wrist, or humerus.

tradeoff between desirable and undesirable outcomes and cost; recommendations require estimating the relative value patients place on the outcomes. We are unaware of published literature exploring patient values and preferences regarding these issues. Our judgments were based on the experience of the Panel members (which included a patient) in shared decision-making with their patients. Below we outline the Voting Panel's assessment of these tradeoffs that informed the final recommendations.

Consensus building. The Voting Panel voted on the direction and strength of the recommendation related to each PICO question. An 80% level of agreement was used as the threshold for a recommendation; if 80% agreement was not achieved during an initial vote, the Panel members held additional discussions before re-voting. Consistent with GRADE guidance, in some instances the Voting Panel chose to provide a strong recommendation despite a low quality rating of evidence (33). In such cases, a written explanation is provided, describing the reasons for this decision.

Moving from recommendations to practice. When applying these risk-stratified recommendations in clinical settings, adults ≥40 years of age receiving long-term GCs should be designated as being at moderate-to-high risk or low risk of fracture (Table 1) based on BMD, history of fracture, and 10-year risk of major OP fracture and hip fracture calculated using a tool that combines risk factors with GC dose. Although many tools that incorporate GC use are available, the Voting Panel suggested using FRAX (https://www.shef.ac.uk/FRAX/tool.jsp) for fracture risk assessment. When GC use is included as a risk factor in FRAX, the fracture risk generated is the risk associated with a prednisolone dose of 2.5–7.5 mg/day (prednisolone and prednisone doses are nearly equivalent). For people receiving doses of >7.5 mg/day, the fracture risk generated with FRAX should be increased by a relative 15% for major osteoporotic fracture and 20% for hip fracture risk (13). For example, if the 10-year hip fracture risk is 2.0% with GC use entered in FRAX, the risk estimate should be increased to 2.4% if the prednisone dose is >7.5 mg.

There are no tools available to estimate absolute fracture risk in children or in adults <40 years of age. These groups were considered to be at high fracture risk if they have previously sustained an OP fracture. The Voting Panel designated men and women <40 years of age to be at moderate risk if they were expected to continue GC treatment at >7.5 mg/day for 6 months and had either 1) a hip or spine BMD Z score of <−3 or 2) a rapid decline in hip or spine BMD (equivalent to ≥10% in 1 year) during GC treatment.

RESULTS/RECOMMENDATIONS

How to interpret the recommendations

1. The Voting Panel's assessment was that patients would be willing to take calcium and vitamin D with only a very small absolute risk reduction, that all or virtually all would be willing to take bisphosphonates to achieve a 5-year absolute reduction in vertebral fracture risk of 5%, and that most would choose to take oral bisphosphonates if the fracture

reduction were ≥3% to <5% (leading to a conditional recommendation in favor). The 5-year time period was chosen because few clinical trials have data on fracture risk reduction past 3–5 years. Further, the Panel members thought that most patients would decline oral bisphosphonates with an absolute reduction in 5-year risk of vertebral fractures of 1.6–2.9% (leading to a conditional recommendation against), and all or virtually all would decline if the risk reduction were <1.5% (leading, in the presence of high- or moderate-quality evidence, to a strong recommendation against).

Yes
BMD testing within 6 mo of the start of GC treatment

Figure 1. Initial fracture risk assessment. A clinical fracture risk assessment includes obtaining a history with the details of glucocorticoid (GC) use (dose, duration, pattern of use), an evaluation for falls, fractures, frailty, and other osteoporosis (OP) risk factors (malnutrition, significant weight loss or low body weight, hypogonadism, secondary hyperparathyroidism, thyroid disease, family history of hip fracture, history of alcohol use [at ≥3 units/day] or smoking) and other clinical comorbidities, and a physical examination including measurement of weight and height (without shoes), testing of muscle strength, and assessment for other clinical findings of undiagnosed fracture (i.e., spinal tenderness, deformity, and reduced space between lower ribs and upper pelvis) as appropriate given the patient's age. The risk of major osteoporotic fracture calculated with the FRAX tool (https://www.shef.ac.uk/FRAX/tool.jsp) should be increased by 1.15, and the risk of hip fracture by 1.2, if the prednisone dose is >7.5 mg/day (e.g., if the calculated hip fracture risk is 2.0%, increase to 2.4%). It is recognized that in some cases, bone mineral density (BMD) testing may not be available.

For intravenous (IV) bisphosphonates, denosumab, raloxifene, and teriparatide, which have greater harms or burden of treatment, the threshold was higher, although the Panel did not specify a threshold value. Because raloxifene may increase the risk of death due to stroke in postmenopausal women with documented coronary heart disease or at increased risk of major coronary events and/or may increase the risk of deep vein thrombosis and pulmonary embolism (35), and there is no evidence of its benefit in fracture reduction in GC-treated patients, the Voting Panel considered the drug as a treatment option only for postmenopausal women with contraindications to all other treatments. We are unaware of published literature exploring patient values and preferences regarding these issues. The judgments are based on the experience of the Panel members (which included a patient) in shared decision-making with their patients.

2a. A *strong recommendation* means that the Panel was *confident* that the desirable effects of following the recommendation outweigh the undesirable effects (or vice versa), so the course of action would apply to all or almost all patients, and only a small proportion would not want to follow the recommendation.

2b. A *conditional recommendation* means that the Panel believed the desirable effects of following the recommendation *probably* outweigh the undesirable effects, so the course of action would apply to the majority of the patients, but some may not want to follow the recommendation. Because of this, conditional recommendations are preference sensitive and always warrant a shared decision-making approach.

2c. A *good practice recommendation* (36) means that although the Panel believed the benefits of proceeding according to the guidance far outweigh the harms, the supporting evidence is indirect, and the Panel did not formally assess the relevant evidence. The logic for the good practice statements is as follows: Appropriate management regarding bone health is based on an initial assessment and reassessment of fracture risk. However, there are inadequate data directly addressing outcomes in patients whose cases were managed with, versus those without, initial and follow-up fracture risk assessments. The chain of evidence—limited antifracture treatment with limited adverse effects in those at low risk; more aggressive antifracture treatment with resultant decrease in fractures in those at high risk—is nevertheless compelling, though without a structured review of the evidence for the benefits and harms, the statement in question does not warrant a formal GRADE recommendation.

3. For each recommendation, details regarding the PICO questions and the GRADE evidence tables are listed in Supplementary Appendices 1 and 3 (on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract).

4. Recommendations for BMD testing are based on the assumption that it is available in the region where the patient receives treatment and that there are no significant barriers, including the patient's functional status or financial barriers, that preclude testing, and that the results are likely to have an impact on clinical decision-making.

Recommendations for fracture risk assessment and reassessment

Initial fracture risk assessment. All of the fracture risk assessment and reassessment recommendations are made as good practice recommendations. In all adults and children, an *initial clinical fracture risk assessment should be performed as soon as possible, but at least within 6 months of the initiation of long-term GC treatment* (Figure 1). This assessment should include a history with the details of GC use (dose, duration, pattern of use), an evaluation for falls, fractures, frailty, and other risk factors for fracture (malnutrition, significant weight loss or low body weight, hypogonadism, secondary hyperparathyroidism, thyroid disease, family history of hip fracture, history of alcohol use [at $\geq$3 units/day] or smoking) and other clinical comorbidities, and a physical examination including measurement of weight and height (without shoes), testing of muscle strength, and assessment for other clinical findings of undiagnosed fracture (i.e., spinal tenderness, deformity, and reduced space between lower ribs and upper pelvis) as appropriate given the patient's age.

In addition, for adults $\geq$40 years of age, the initial absolute fracture risk should be estimated using FRAX (https://www.shef.ac.uk/FRAX/tool.jsp) with the adjustment for GC dose and BMD testing (if available, or without BMD if it is not available) as soon as possible, but at least within 6 months of the initiation of GC treatment.

For adults $<$40 years of age, BMD testing should be done as soon as possible but at least within 6 months of the initiation of GC treatment if the patient is at high fracture risk because of a history of previous OP fracture(s) or if the patient has other significant OP risk factors (malnutrition, significant

Figure 2. Reassessment of fracture risk. A clinical fracture risk reassessment includes obtaining a history with the details of glucocorticoid (GC) use (dose, duration, pattern of use), an evaluation for falls, fractures, frailty, and other osteoporosis (OP) risk factors (malnutrition, significant weight loss or low body weight, hypogonadism, secondary hyperparathyroidism, thyroid disease, family history of hip fracture, history of alcohol use [at ≥3 units/day] or smoking) and other clinical comorbidities, and a physical examination including measurement of weight and height (without shoes), testing of muscle strength, and assessment for other clinical findings of undiagnosed fracture (i.e., spinal tenderness, deformity, and reduced space between lower ribs and upper pelvis) as appropriate given the patient's age. Very high-dose GC treatment was defined as treatment with prednisone ≥30 mg/day and a cumulative dose of >5 gm in the past year. Reliability of FRAX (https://www.shef.ac.uk/FRAX/tool.jsp) after OP treatment is debated, but FRAX calculation can be repeated in adults age ≥40 years who have not received treatment. It is recognized that in some cases, bone mineral density (BMD) testing may not be available.

weight loss or low body weight, hypogonadism, secondary hyperparathyroidism, thyroid disease, family history of hip fracture, smoking, alcohol use at ≥3 units/day).

Reassessment of fracture risk. In all adults and children who continue GC treatment, a *clinical fracture risk reassessment should be performed every 12 months* (Figure 2).

Adults ≥40 years of age. For adults ≥40 years of age who continue GC treatment and are *not treated with an OP medication beyond calcium and vitamin D,* reassessment with FRAX, with BMD testing if available,

Table 2. Recommendations for initial treatment for prevention of GIOP in adults (women not of child-bearing potential and men) beginning long-term GC treatment*

All adults taking prednisone at a dose of ≥2.5 mg/day for ≥3 months

Optimize calcium intake (1,000–1,200 mg/day)* **and vitamin D intake** (600–800 IU/day) **and lifestyle modifications** (balanced diet, maintaining weight in the recommended range, smoking cessation, regular weight-bearing or resistance training exercise, limiting alcohol intake to 1–2 alcoholic beverages/day) **over no treatment or over any of these treatments alone.**

Conditional recommendation because of indirect evidence on the impact of lifestyle modifications on fracture risk, low-quality evidence on the impact of calcium and vitamin D on fractures in GC users, and indirect evidence on the benefit of calcium and vitamin D on fracture risk in the general OP population

Adults age ≥40 years at low risk of fracture

Optimize calcium and vitamin D intake and lifestyle modifications over treatment with bisphosphonates, teriparatide, denosumab, or raloxifene.

Conditional recommendation for calcium and vitamin D over oral bisphosphonates, teriparatide, and denosumab because of low-quality evidence on additional antifracture benefit of the alternative treatments in this low-risk group, costs, and potential harms

Strong recommendation for calcium and vitamin D over IV bisphosphonates and raloxifene because of low-quality evidence on additional antifracture benefit in this low-risk group and their potential harms

Adults age ≥40 years at moderate risk of major fracture

Treat with an oral bisphosphonate over calcium and vitamin D alone.

Treat with an oral bisphosphonate over IV bisphosphonates, teriparatide, denosumab, or raloxifene.

Oral bisphosphonates preferred for safety, cost, and because of lack of evidence of superior antifracture benefits from other OP medications.
Other therapies if oral bisphosphonates are not appropriate, in order of preference:
- IV bisphosphonates
  - Higher risk profile for IV infusion over oral bisphosphonate therapy
- Teriparatide
  - Cost and burden of therapy with daily injections
- Denosumab
  - Lack of safety data in people treated with immunosuppressive agents
- Raloxifene (for postmenopausal women in whom none of the medications listed above is appropriate)
  - Lack of adequate data on benefits (impact on risk of vertebral and hip fractures in GC users) and potential harms (clotting risks, mortality)

Conditional recommendations because of indirect and low-quality evidence comparing benefits and harms of alternative treatments in people with moderate fracture risk

Adults age ≥40 years at high risk of fracture

Treat with an oral bisphosphonate over calcium and vitamin D alone.

Treat with an oral bisphosphonate over IV bisphosphonates, teriparatide, denosumab, or raloxifene.

Oral bisphosphonates preferred for safety, cost, and because of lack of evidence of superior antifracture benefits from other OP medications.
Other therapies if oral bisphosphonates are not appropriate, in order of preference:
- IV bisphosphonates
  - Higher risk profile for IV infusion over oral bisphosphonate therapy
- Teriparatide
  - Cost and burden of therapy with daily injections
- Denosumab
  - Lack of safety data in people treated with immunosuppressive agents
- Raloxifene (for postmenopausal women in whom none of the medications listed above is appropriate)
  - Lack of adequate data on benefits (impact on risk of vertebral and hip fractures in GC users) and potential harms (clotting risks, mortality)

Strong recommendation for oral bisphosphonates over calcium and vitamin D alone because of the strength of the indirect evidence of antifracture efficacy and low harms

All other recommendations **conditional** because of indirect and low-quality evidence comparing benefits and harms of alternative treatments in people with high fracture risk

Adults age <40 years at low risk of fracture

Optimize calcium and vitamin D intake and lifestyle modifications over treatment with bisphosphonates, teriparatide, or denosumab.

Conditional recommendation for calcium and vitamin D over oral bisphosphonates, teriparatide, and denosumab because of low-quality evidence on additional antifracture benefit of the alternative treatments, costs, and potential harms

Strong recommendation for calcium and vitamin D over IV bisphosphonates because of low-quality evidence for additional antifracture benefit in this low-risk group and potential harms

*Correction added after online publication 27 September 2017: the dosage for optimized calcium intake has been changed from 800–1,000 mg/day to 1,000–1,200 mg/day.

Table 2. *(Cont'd)*

Adults age <40 years at moderate-to-high risk of fracture
Treat with an oral bisphosphonate over calcium and vitamin D alone.
Treat with an oral bisphosphonate over IV bisphosphonates, teriparatide, or denosumab.
Oral bisphosphonates preferred for safety, cost, and because of lack of evidence of superior antifracture benefits from other OP medications. Other therapies if oral bisphosphonates are not appropriate, in order of preference: IV bisphosphonates Higher risk profile for IV infusion over oral bisphosphonate therapy Teriparatide Cost and burden of therapy with daily injections Denosumab Lack of safety data in people treated with immunosuppressive agents
Conditional recommendations because of low- to very low-quality evidence on absolute fracture risk and indirect and low-quality evidence comparing relative harms and benefits of alternative treatments in this age group

* GIOP = glucocorticoid (GC)–induced osteoporosis; IV = intravenous.

should be completed every 1–3 years. This reassessment should be performed earlier within this 1–3-year time range for adults age ≥40 years who are receiving very high doses of GCs (initial prednisone dose ≥30 mg/day, cumulative dose >5 gm in the previous year) or those with a history of OP fracture(s). Later or less frequent testing within this range can be done for adults age ≥40 years who are taking lower doses of GCs with no other OP risk factors.

For adults ≥40 years old who continue GC treatment and are *currently treated with an OP medication in addition to calcium and vitamin D*, BMD testing should be completed every 2–3 years during treatment in high-risk patients such as those receiving very high-dose GCs (initial prednisone dose ≥30 mg/day, cumulative dose >5 gm in the previous year), a history of OP fracture occurring after ≥18 months of treatment with antifracture medication (other than calcium and vitamin D), risks for poor medication adherence or absorption, or other significant OP risk factors.

For adults ≥40 years old who *received an OP treatment in the past but are no longer being treated with an OP medication other than calcium and vitamin D,* BMD testing should be done every 2–3 years. Within this range, reassessment should be conducted earlier in patients receiving higher doses of GCs and those with a history of fracture or low BMD, and later in those receiving lower doses of GCs, with higher BMD and no other OP risk factors.

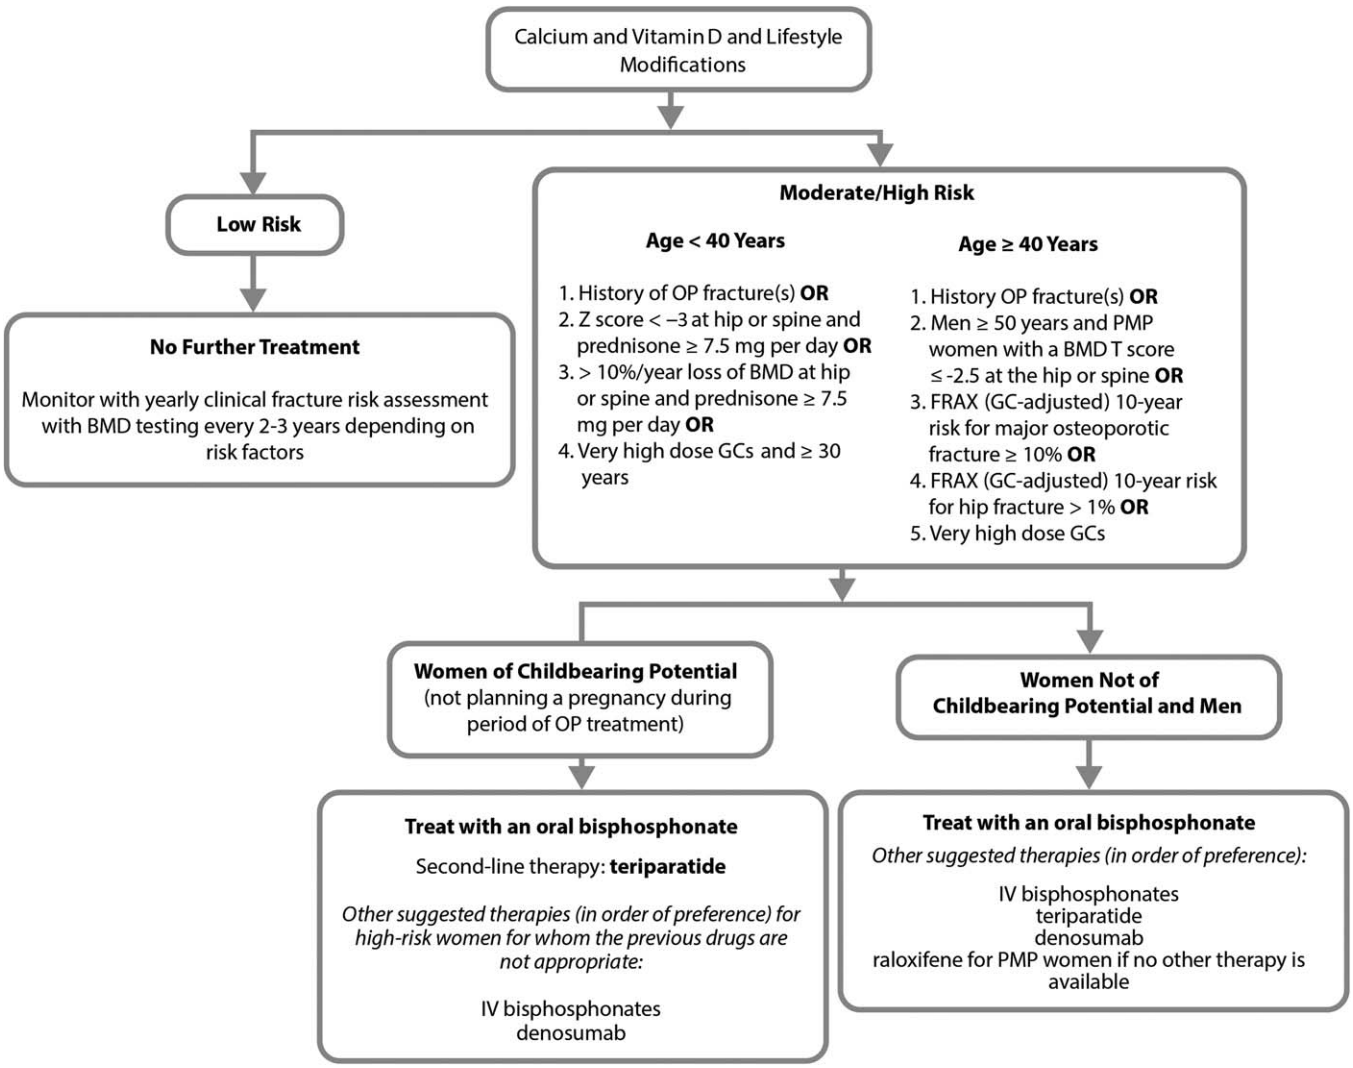
Adults <40 years of age. For all adults <40 years of age who continue GC treatment and are *at moderate-to-high fracture risk* (history of previous fracture, BMD Z score <−3, received very high-dose prednisone [≥30 mg/day and cumulative dose >5 gm] in the previous year, risks for poor medication adherence or absorption, or multiple OP risk factors), BMD testing should be done every 2–3 years.

Recommendations for treatment

The Voting Panel's rationale and strength of recommendations for treatment are detailed in Table 2.

Calcium and vitamin D intake and lifestyle modifications. Optimizing calcium intake (1,000–1,200 mg/day) and vitamin D intake (600–800 IU/day; serum level ≥20 ng/ml) (37) as well as lifestyle modifications (a balanced diet, maintaining weight in the recommended range, smoking cessation, regular weight-bearing or resistance training exercise, limiting alcohol intake to 1–2 alcoholic beverages/day) are conditionally recommended for all patients receiving GC treatment.

Initial pharmacologic treatment. *Adults ≥40 years of age.* Women ≥40 years of age and not of childbearing potential and men ≥40 years of age (Figure 3) who are at moderate-to-high risk of fracture should be treated with an oral bisphosphonate (strong recommendation for those at high risk; conditional recommendation for those at moderate risk). For patients in whom oral bisphosphonates are not appropriate (for example, due to comorbidities, patient preference, or concerns about adherence with an oral medication regimen), IV bisphosphonates should be used rather than the patient receiving no additional treatment beyond calcium and vitamin D. If bisphosphonate treatment is not appropriate, teriparatide should be used rather than the patient receiving no additional treatment beyond calcium and vitamin D. If neither oral nor IV bisphosphonates nor teriparatide treatment is appropriate, denosumab should be used rather than the patient receiving no additional treatment beyond calcium and



Calcium and Vitamin D and Lifestyle Modifications
Low Risk
No Further Treatment
Monitor with yearly clinical fracture risk assessment with BMD testing every 2-3 years depending on risk factors
Moderate/High Risk
Age < 40 Years
1. History of OP fracture(s) OR
2. Z score < –3 at hip or spine and prednisone ≥ 7.5 mg per day OR
3. > 10%/year loss of BMD at hip or spine and prednisone ≥ 7.5 mg per day OR
4. Very high dose GCs and ≥ 30 years
Age ≥ 40 Years
1. History OP fracture(s) OR
2. Men ≥ 50 years and PMP women with a BMD T score ≤ -2.5 at the hip or spine OR
3. FRAX (GC-adjusted) 10-year risk for major osteoporotic fracture ≥ 10% OR
4. FRAX (GC-adjusted) 10-year risk for hip fracture > 1% OR
5. Very high dose GCs
Women of Childbearing Potential (not planning a pregnancy during period of OP treatment)
Women Not of Childbearing Potential and Men
Treat with an oral bisphosphonate
Second-line therapy: teriparatide
Other suggested therapies (in order of preference) for high-risk women for whom the previous drugs are not appropriate:
IV bisphosphonates
denosumab
Treat with an oral bisphosphonate
Other suggested therapies (in order of preference):
IV bisphosphonates
teriparatide
denosumab
raloxifene for PMP women if no other therapy is available

Figure 3. Initial pharmacologic treatment for adults. Recommended doses of calcium and vitamin D are 1,000–1,200 mg/day and 600–800 IU/day (serum level ≥20 ng/ml), respectively. Lifestyle modifications include a balanced diet, maintaining weight in the recommended range, smoking cessation, regular weight-bearing and resistance training exercise, and limiting alcohol intake to 1–2 alcoholic beverages/day. Very high-dose glucocorticoid (GC) treatment was defined as treatment with prednisone ≥30 mg/day and a cumulative dose of >5 gm in the past year. The risk of major osteoporotic (OP) fracture calculated with the FRAX tool (https://www.shef.ac.uk/FRAX/tool.jsp) should be increased by 1.15, and the risk of hip fracture by 1.2, if the prednisone dose is >7.5 mg/day (e.g., if the calculated hip fracture risk is 2.0%, increase to 2.4%). It is recognized that in some cases, bone mineral density (BMD) testing may not be available. PMP = postmenopausal; IV = intravenous.

vitamin D. For postmenopausal women in whom none of these medications is appropriate, raloxifene should be used rather than the patient receiving no additional treatment beyond calcium and vitamin D. The order of the preferred treatments was determined based on a comparison of efficacy (fracture reduction), toxicity, and cost. These are conditional recommendations.

Adults <40 years of age. For adults <40 years of age (women not of childbearing potential and men) (Figure 3) with a history of OP fracture, or those continuing GC treatment (≥6 months at a dose of ≥7.5 mg/day) who have either a hip or spine BMD Z score < -3 or bone loss of ≥10%/year at the hip or spine as assessed by dual x-ray absorptiometry (DXA), an oral bisphosphonate should

Table 3. Recommendations for initial treatment for prevention of GIOP in special populations of patients beginning long-term GC treatment*

Women of childbearing potential at moderate-to-high risk of fracture (Table 1) who do not plan to become pregnant within the period of OP treatment and are using effective birth control or are not sexually active

Treat with an oral bisphosphonate over calcium and vitamin D alone, teriparatide, IV bisphosphonates, or denosumab.

Oral bisphosphonates preferred for safety, cost, and because of lack of evidence of superior antifracture benefits from other OP medications.
Other therapies if oral bisphosphonates are not appropriate, in order of preference:
- Teriparatide
  - Safety, cost, and burden of therapy with daily injections

Consider the following therapies only for **high-risk** patients because of lack of safety data on use of these agents during pregnancy:
- IV bisphosphonates
  - Potential fetal risks of IV infusion during pregnancy
- Denosumab
  - Potential fetal risks during pregnancy

Conditional recommendations because of indirect and very low-quality evidence on benefits and harms of these treatments to the fetus during pregnancy

Adults age ≥30 years receiving very high-dose GCs (initial dose of prednisone ≥30 mg/day and cumulative dose >5 gm in 1 year)

Treat with an oral bisphosphonate over calcium and vitamin D alone.

Treat with an oral bisphosphonate over IV bisphosphonates, teriparatide, or denosumab.

Oral bisphosphonates preferred for safety, cost, and because of lack of evidence of additional antifracture benefits from other OP medications.

If bisphosphonate treatment is not appropriate, alternative treatments are listed by age (≥40 years and <40 years) in Table 2.

Conditional recommendations because of low-quality evidence on absolute fracture risk and harms in this population

Adults with organ transplant, glomerular filtration rate ≥30 ml/minute, and no evidence of metabolic bone disease who continue treatment with GCs

Treat according to the age-related guidelines for adults without transplants (Table 2), with these additional recommendations:

An evaluation by an expert in metabolic bone disease is recommended for all patients with a renal transplant.

Recommendation against treatment with denosumab due to lack of adequate safety data on infections in adults treated with multiple immunosuppressive agents.

Conditional recommendations because of low-quality evidence on antifracture efficacy in transplant recipients and on relative benefits and harms of the alternative treatments in this population

Children ages 4–17 years treated with GCs for ≥3 months

Optimize calcium intake (1,000 mg/day) and vitamin D intake (600 IU/day) and lifestyle modifications over not optimizing calcium and vitamin D intake and lifestyle modifications.

Conditional recommendation because of lack of antifracture efficacy of calcium and vitamin D in children but limited harms

Children ages 4–17 years with an osteoporotic fracture who are continuing treatment with GCs at a dose of ≥0.1 mg/kg/day for ≥3 months

Treat with an oral bisphosphonate (IV bisphosphonate if oral treatment contraindicated) plus calcium and vitamin D over treatment with calcium and vitamin D alone.

Conditional recommendation because of very low-quality antifracture data in children but moderate-quality evidence of low harms of oral bisphosphonates in children and less potential harm of oral over IV bisphosphonates

* GIOP = glucocorticoid (GC)–induced osteoporosis; IV = intravenous.

be used rather than the patient receiving no additional treatment beyond calcium and vitamin D. If treatment with an oral bisphosphonate is not appropriate, the same alternative medications listed for adults ≥40 years of age are recommended with the exception of raloxifene, which is not used in men and premenopausal women. These are conditional recommendations.

Special populations. For women who meet criteria for *moderate-to-high risk of fracture* (Table 1) and are of *childbearing potential* (Table 3 and Figure 3), *but do not plan to become pregnant within the period of OP treatment and are using effective birth control or are not sexually active,* an oral bisphosphonate should be used rather than the patient receiving no additional treatment beyond calcium and vitamin D. If oral bisphosphonate treatment is not appropriate, teriparatide should be used rather than the patient receiving no additional treatment beyond calcium and vitamin D. Because of the lack of safety data and the potential fetal harm associated with denosumab in animal studies and with high-dose IV bisphosphonates (38–53), these therapies should be used only in women who are at high risk of fracture in whom treatment with an oral bisphosphonate and teriparatide is not appropriate. Denosumab or IV bisphosphonate treatment should be initiated only after a discussion with the patient about the very low quality of evidence about fetal harms in the event of an unplanned pregnancy. These are conditional recommendations.

There is a lack of data on the safety of currently available OP treatments during pregnancy. Therefore, these guidelines do not include recommendations about OP prevention or treatment, other than calcium and vitamin D intake and lifestyle modification, in women who are pregnant.

For *adults ≥30 years of age who are receiving very high-dose GC treatment* (initial prednisone dose of ≥30 mg/day [or equivalent GC exposure] and a cumulative annual dose of >5 gm) (Table 3), oral bisphosphonate treatment should be initiated. If treatment with an oral bisphosphonate is not appropriate, the age-related recommendations for second-line therapy (Table 2) should be followed (with adjustments for women of childbearing potential as outlined in these guidelines). These are conditional recommendations.

For adults *who have received an organ transplant and who are continuing treatment with GCs* (Table 3),

Table 4. Recommendations for follow-up treatment for prevention of GIOP*

Adults age ≥40 years continuing GC treatment who have had a fracture that occurred after ≥18 months of treatment with an oral bisphosphonate or who have had a significant loss of bone mineral density (≥10%/year)

Treat with another class of OP medication (teriparatide or denosumab; or, consider IV bisphosphonate if treatment failure is judged to be due to poor absorption or poor medication adherence) with calcium and vitamin D over calcium and vitamin D alone or over calcium and vitamin D and continued oral bisphosphonate.

Conditional recommendation because of very low-quality evidence comparing benefits and harms of the compared treatment options in this clinical situation

Adults age ≥40 years who have completed 5 years of oral bisphosphonate treatment and who continue GC treatment and are assessed to be at moderate-to-high risk of fracture

Continue active treatment (with an oral bisphosphonate beyond 5 years or switch to IV bisphosphonate [if concern with regard to adherence or absorption] or switch to an OP treatment in another class) over calcium and vitamin D alone.

Conditional recommendation because of very low-quality data on benefits and harms in GC-treated patients, but moderate-quality data in the general OP literature on benefits and harms of continuing treatment with oral bisphosphonates past 5 years for people at high risk of fracture

Adults age ≥40 years taking an OP medication in addition to calcium and vitamin D who discontinue GC treatment and are assessed to be at low risk of fracture

Discontinue the OP medication but continue calcium and vitamin D over continuing the OP medication.

Conditional recommendation made by expert consensus; evidence informing it too indirect for the population and very low-quality

Adults age ≥40 years taking an OP medication in addition to calcium and vitamin D who discontinue GC treatment and are assessed to be at moderate-to-high risk of fracture

Complete the treatment with the OP medication over discontinuing the OP medication.

Strong recommendation for high-risk patients based on expert consensus that patients who are at high risk should continue an OP treatment in addition to calcium and vitamin D

Conditional recommendation for moderate-risk patients because of lower fracture risk compared to potential harms

* GIOP = glucocorticoid (GC)–induced osteoporosis; IV = intravenous.

the age-related treatment recommendations outlined in these guidelines for men and women who do not have transplants should be followed if the glomerular filtration rate is ≥30 ml/minute and there is no evidence of metabolic bone disease. An evaluation by an expert in metabolic bone disease is recommended before initiating pharmacologic treatment in adults with a renal transplant (54). The Panel made a recommendation against the use of denosumab because of lack of safety data in this population of patients who are treated with multiple immunosuppressive agents. These are conditional recommendations.

For *GC-treated children 4–17 years of age,* a calcium intake of 1,000 mg/day and vitamin D intake of 600 IU/day is recommended. For children who have had an OP fracture who continue GC treatment at a dose of ≥0.1 mg/kg/day for ≥3 months, treatment with an oral bisphosphonate (or an IV bisphosphonate if oral treatment is not appropriate) is recommended (Table 3). These are conditional recommendations.

Follow-up treatment recommendations. *Initial treatment failure.* For adults ≥40 years of age who are continuing GC treatment who have had a fracture that occurred ≥18 months after beginning treatment with an oral bisphosphonate or had a significant decline in BMD (≥10%/year) after 1 year of treatment (Table 4), treatment with another class of OP medication (teriparatide, denosumab) or an IV bisphosphonate (if treatment failure is judged to be due to poor absorption or poor medication adherence) is recommended rather than the patient receiving no additional treatment beyond calcium and vitamin D alone or continuing oral bisphosphonate treatment. These are conditional recommendations.

Treatment if moderate-to-high fracture risk persists after bisphosphonate therapy. For adults ≥40 years of age who have completed 5 years of oral bisphosphonate treatment (Table 4) who are continuing GC treatment and are assessed to be at moderate-to-high risk of fracture (Table 1), continuation of active OP treatment (in addition to calcium and vitamin D) is recommended rather than the patient receiving no additional treatment beyond calcium and vitamin D. Suggested treatment options include continuing the oral bisphosphonate for 7–10 years, switching to an IV bisphosphonate if absorption or adherence is a problem, or treatment with another class of OP medication (teriparatide or denosumab), depending on the response to the initial bisphosphonate treatment (change in BMD, new fractures) and with consideration of rare risks, including jaw necrosis and atypical femur fractures, which might increase with the duration of antiresorptive therapy. These are conditional recommendations.

Treatment if GCs are discontinued. For adults ≥40 years of age who are treated with OP medication in addition to calcium and vitamin D and are discontinuing GC treatment (Table 4), discontinuation of the OP medication is recommended if fracture risk at the time of GC discontinuation is assessed to be low. Otherwise, the OP treatment course should be completed or continued until the fracture risk is assessed to be low. Continuation of OP treatment in the setting of high risk is a strong recommendation. The others are conditional recommendations.

Application of these treatment recommendations. These recommendations are made for average or typical GC-treated patients. They may not be applicable to GC-treated patients with multiple risk factors or feasible for patients with financial or social barriers to testing and treatment.

DISCUSSION

This report presents the updated ACR recommendations for the prevention and treatment of osteoporosis and fractures in patients receiving glucocorticoid treatment. The goal is to optimize identification of patients at risk of GC-induced fractures so that they can be appropriately treated while limiting the risk and the burden of testing and treatment. The guiding principle for these guidelines was to use outcome measures that are clinically relevant to patients and providers, so in decision-making, data about absolute fracture risk reduction were given priority over BMD changes. The recommendations on the order of first-line treatments were based on the Voting Panel's assessment of antifracture efficacy, potential harms, and costs. Thus, oral bisphosphonates were recommended as the preferred first-line therapy in most clinical situations given their antifracture benefit, safety, and low cost, unless there are contraindications, intolerance, or concerns about patient adherence to treatment.

Robust methodology was used in the literature search. The Voting Panel had a broad representation of clinicians, both primary care providers and subspecialists, with experience in bone health and in prescribing GC medications. In addition, these guidelines include recommendations for the assessment and reassessment of fracture risk and antifracture therapy during GC treatment and for special populations, such as children, people with organ transplants, people receiving very high doses of GCs, and women of childbearing potential.

There are limitations to these recommendations. First, many important clinical situations could not be addressed given the limited scope of this guideline

project. Recommendations addressing initial assessment and reassessment of fracture risk were made as good practice recommendations (36) because, although the Panel believes that the benefits of proceeding according to the guidance far outweigh the undesirable consequences, the supporting evidence is indirect or not available, and the Panel did not formally gather, summarize, or assess the relevant evidence.

We adopted generally accepted thresholds to define high, medium, and low levels of absolute risk of incident fracture (i.e., <10%, 10–19%, and ≥20% 10-year risk of major osteoporotic fracture). These cut points were used to stratify PICO questions and weigh potential benefits versus harms in those different clinical situations. However, the application of these recommendations to a clinical setting requires that the physician assign the individual patient into a risk stratum. For adults age ≥40 years, this can be accomplished using fracture risk calculators that take the GC dose into account, such as the FRAX tool. However, FRAX has important limitations. First, the fracture risk generated when GC use is included as a risk factor estimates the risk that would be associated with moderate-dose prednisone (2.5–7.5 mg/day). To accurately estimate the risk associated with doses of >7.5 mg/day, the clinician must multiply the risk of major osteoporotic fracture and the risk of hip fracture generated with the FRAX by 1.15 and by 1.2, respectively. This adjustment may not adequately estimate the risk associated with very high-dose GC use. FRAX uses hip BMD to calculate fracture risk, but GC use has a greater impact on spine BMD. For GC-treated patients with discordant spine and hip BMD (with lower spine BMD), the Fracture Risk Calculator, which includes spine BMD in absolute fracture risk estimation, is available (https://riskcalculator.fore.org). Finally, there is debate about the validity of FRAX fracture risk estimates after pharmacologic treatment for OP, which should be considered in the reassessment of fracture risk in treated patients.

The available evidence about fracture risk and risk reduction was particularly limited with regard to treatment recommendations in adults <40 years of age and children, and there are no tools available to estimate absolute fracture risk in these age groups. Younger people are often treated with higher doses of GCs, but they have higher bone mass and greater potential for recovery of bone mass when the GC treatment is discontinued. To try to better categorize fracture risk in adults <40 years of age, the Panel considered several risk factors as indicators of moderate-to-high fracture risk—including history of previous fragility fracture, significant decrease in BMD, or low BMD Z score with continued use of prednisone (limiting the recovery of bone mass) at a dose of ≥7.5 mg/day for at least 6 months—in patients <40 years old, as well as in patients ≥30 years old treated with very high doses of GCs (initial prednisone dose ≥30 mg/day with a cumulative dose of >5 gm) (15,18,21–25). The lack of data on long-term outcomes with OP treatment in this age group may lead to under- or overtreatment, but the possible benefits to long-term bone health and the relatively low risks associated with the recommended OP treatments led to the recommendation of treatment with an oral bisphosphonate in addition to calcium and vitamin D. There is a need for more research about absolute risk of fracture in this age group during and after GC use and into later adult life.

Fracture data are very limited in GIOP-specific clinical trials and population studies. Lacking these data, the relative fracture reduction associated with OP medications was extrapolated from the risk reduction ascertained in clinical trials of many different treatments for OP in general. While this step introduced indirectness into the quality of evidence for many PICO questions, it is reassuring that where parallel data from GIOP and non-GIOP trials exist, the derived relative risks for treatment effects from the same intervention are often similar, indicating that the assumption of generalizability may be reasonable (Supplementary Appendix 3 [Summary of Findings Tables 1.4a/b/c, 1.9a/b/c], available on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.40137/abstract). Imprecision in the estimate of benefits of treatment is increased by these extrapolations. Future clinical trials in GC-treated patients should include fracture as a primary outcome measure.

The Panel faced low-quality evidence regarding the magnitude of benefit GC-treated patients would require as a tradeoff for assuming the burden and risks of treatment for lowering fracture risk, particularly given the uncertainties associated with estimates of benefit. Awareness of the need to attain "minimally disruptive medicine" (55) has increased in recent years, and many of the candidate patients already bear the burden of multiple medications. This burden may influence their willingness to tolerate yet additional treatment. The Panel's assessment was that patients would be willing to take calcium and vitamin D with only a very small absolute risk reduction, that all or virtually all would be willing to take bisphosphonates to achieve a 5-year absolute reduction in vertebral fracture risk of 5%, and that most would choose to take oral bisphosphonates if the fracture reduction were between ≥3% and <5%. Patients who value these small absolute reductions less

highly than the Panel estimated may decide against recommended treatment after discussion of risks and benefits with their providers.

There are concerns about the potential harms of calcium and vitamin D supplementation with regard to cardiovascular risks (56,57). Optimizing calcium intake, however, may be even more important in GC-treated patients because of the increase in urinary calcium excretion during GC use. For this reason, the guidelines suggest optimizing dietary intake of calcium. More research about the benefits and harms of supplemental calcium and vitamin D in GC-treated patients is needed.

Because of these limitations, most of the recommendations in this guideline are conditional or good clinical practice recommendations. Further studies are needed to examine differences in fracture risk in people with different OP risk factors (age, race, and sex), the role of spine imaging using vertebral fracture assessment with DXA or radiography in assessing fracture risk in GC users, the risk of OP medications to the fetus in women of childbearing potential, and the impact of OP treatment versus no treatment on adult bone health and fracture risk in GC-treated children.

GIOP is not a problem that is unique to rheumatology; GCs are widely prescribed by primary care providers and subspecialists. The Panel's judgments regarding patients' values and preferences were informed by input from the primary care physicians, non-rheumatology specialists, and the patient who served on the Panel. This patient highlighted the significant challenges that patients and clinicians confront when making decisions about optimizing bone health during GC treatment of chronic inflammatory conditions.

ACKNOWLEDGMENTS

We thank Jonathan (Rick) Adachi, MD, Robert Adler, MD, Marcy Bolster, MD, Roberto Civitelli, MD, Jeffrey Curtis, MD, MPH, Chad Deal, MD, Michael Maricic, MD, Clifford Rosen, MD, Kenneth Saag, MD, MSc, Emily von Scheven, MD, and Barton Wise, MD for serving on the Expert Panel. We thank Tom Nickolas, MD, MS, and Elizabeth Shane, MD for providing expert advice. We thank the Arthritis Foundation for its assistance with patient involvement in this guideline project, as well as the patients who participated in this project. We thank the ACR staff, including Ms Regina Parker for assistance in organizing the face-to-face meeting and coordinating the administrative aspects of the project, Ms Robin Lane for assistance in manuscript preparation, and Ms Lauren Evans for assistance throughout the literature review process. We thank Ms Janet Joyce for help in developing the literature search strategy and performing the literature search and updates, and Ms Tamara Radar for peer reviewing the literature search strategy.

AUTHOR CONTRIBUTIONS

All authors were involved in drafting the article or revising it critically for important intellectual content, and all authors approved the final version to be published. Dr. Buckley had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study conception and design. Buckley, Guyatt, Fink, Cannon, Grossman, Hansen, Humphrey, Lane, Magrey, M. Miller, Morrison, Rao, Robinson, Saha, Wolver, Bannuru, Vaysbrot, Osani, Turgunbaev, A. S. Miller, McAlindon.

Acquisition of data. Buckley, Guyatt, Fink, Bannuru, Vaysbrot, Osani, Turgunbaev, A. S. Miller, McAlindon.

ABSTRACT

The therapeutic management of Sjögren syndrome (SjS) has not changed substantially in recent decades: treatment decisions remain challenging in clinical practice, without a specific therapeutic target beyond the relief of symptoms as the most important goal. In view of this scenario, the European League Against Rheumatism (EULAR) promoted and supported an international collaborative study (EULAR SS Task Force) aimed at developing the first EULAR evidence and consensus-based recommendations for the management of patients with SjS with topical and systemic medications. The aim was to develop a rational therapeutic approach to SjS patients useful for healthcare professionals, physicians undergoing specialist training, medical students, the pharmaceutical industry and drug regulatory organisations following the 2014 EULAR standardised operating procedures. The Task Force (TF) included specialists in rheumatology, internal medicine, oral health, ophthalmology, gynaecology, dermatology and epidemiology, statisticians, general practitioners, nurses and patient representatives from 30 countries of the 5 continents. Evidence was collected from studies including primary SjS patients fulfilling the 2002/2016 criteria; when no evidence was available, evidence from studies including associated SjS or patients fulfilling previous sets of criteria was considered and extrapolated. The TF endorsed the presentation of general principles for the management of patients with SjS as three overarching, general consensus-based recommendations and 12 specific recommendations that form a logical sequence, starting with the management of the central triplet of symptoms (dryness, fatigue and pain) followed by the management of systemic disease. The recommendations address the use of topical oral (saliva substitutes) and ocular (artificial tear drops, topical non-steroidal anti-inflammatory drugs, topical corticosteroids, topical CyA, serum tear drops) therapies, oral muscarinic agonists (pilocarpine, cevimeline), hydroxychloroquine, oral glucocorticoids, synthetic immunosuppressive agents (cyclophosphamide, azathioprine, methotrexate, leflunomide and mycophenolate), and biological therapies (rituximab, abatacept and belimumab). For each recommendation, levels of evidence (mostly modest) and TF agreement (mostly very high) are provided. The 2019 EULAR recommendations are based on the evidence collected in the last 16 years in the management of primary 2002 SjS patients and on discussions between a large and broadly international TF. The recommendations synthesise current thinking on SjS treatment in a set of overarching principles and recommendations. We hope that the current recommendations will be broadly applied in clinical practice and/or serve as a template for national societies to develop local recommendations.

INTRODUCTION

Sjögren syndrome (SjS), a systemic autoimmune disease that affects 1–23 persons per 10 000 inhabitants in European countries,[1] presents with a wide spectrum of clinical manifestations and autoantibodies. Antinuclear antibodies are the most frequently detected autoantibodies, anti-Ro/SS-A the most specific, and cryoglobulins and hypocomplementaemia the main prognostic markers.[2] The histological hallmark is a focal infiltration of the exocrine glands by lymphocytes, determined by minor labial salivary gland biopsy. The clinical scenario is dominated by sicca syndrome caused by immune-mediated glandular involvement, accompanied by fatigue, musculoskeletal pain and systemic features in a significant percentage of patients, and complicated by lymphoma in around 2%–5% of patients.[3] When SjS appears in a previously healthy person, the disease is classified as primary, while patients with concomitant systemic autoimmune diseases (SAD) are classified as associated (or secondary) SjS; since this distinction only reflects a clinical situation of autoimmune coexistence the term SjS will be throughout the manuscript. SjS patients make substantial use of healthcare services, with a mean annual total direct cost per patient ranging between £2200 in UK and US$20 000 in the USA.[4 5]

The therapeutic management of SjS has not changed substantially in recent decades[6] and is still based on symptomatic treatment of sicca

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

symptomatology and broad-spectrum immunosuppression for systemic disease, with insufficient information on the differential efficacy and safety of the therapeutic options available.[7] Treatment decisions remain challenging in clinical practice, without a specific therapeutic target beyond the relief of symptoms as the most important goal. Therefore there is growing interest in the proposal of clinical guidelines by national scientific societies.[8–11]

In 2010, the European League Against Rheumatism (EULAR) promoted and supported an international collaborative study (EULAR SS Task Force) aimed at developing disease-specific activity indexes in SjS (EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and EULAR Sjögren's syndrome disease activity index (ESSDAI) scores),[12 13] which are now widely used both clinically and in research. A second project, the development of the first EULAR evidence and consensus-based recommendations for the management of patients with SjS with topical and systemic medications, was proposed and launched.

METHODS

After approval of the proposal by the EULAR Executive Committee, the convenor (MR-C) and co-convenors (CV, SB, XM) invited international experts with a solid history of clinical research in SjS (most of whom were previously involved in the ESSDAI/ESSPRI project) to form part of a Steering Committee (SC) and a Task Force (TF), which also included methodologists, patient representatives and individuals from all relevant professional groups (online supplementary appendix 1). The aim was to develop a rational therapeutic approach to SjS patients that would be useful for healthcare professionals, doctors in specialist training, medical students, the pharmaceutical industry and drug regulatory organisations following the 2014 EULAR standardised operating procedures.[14] Industry involvement was not permitted at any stage of the project.

Steering committee

The SC included 13 rheumatologists, four internal medicine, one primary care and one oral health specialists, one epidemiologist, one statistician, one healthcare professional representative and two patient representatives. The SC agreed on some principal considerations upfront: (a) The statements were termed 'recommendations' as opposed to 'guidelines' or 'points to consider' because they offer guidance, which needs to be tailored to meet individual requirements. (b) Some general rules and definitions (overarching principles, general recommendations, definition of sequential therapeutic schedules, severity or refractoriness) cannot be evidence-based and were, therefore based on consensus. (c) The remaining statements were evidence-based, that is, supported by the highest level of evidence possible, limiting statements based only on retrospective data (although for some clinical or therapeutic scenarios with no data in controlled studies, this was allowed if the amount of retrospective data was considered significant and scientifically reliable); recommendations based on data obtained from case reports were not allowed. (d) Evidence was collected from studies including primary SjS patients fulfilling the 2002/2016 criteria (SjS-2002).[15 16] When no evidence was available, evidence from studies including associated SjS, patients fulfilling previous sets of criteria or those including a mix of autoimmune and non-autoimmune aetiologies was considered and extrapolated (online supplementary table S1). (e) The balance between efficacy and side effects was evaluated agent by agent. (f) Although recommendations are primarily supported by the evidence reported in patients with primary SjS, the advice on topical and systemic management contained in these guidelines may be applicable to patients with associated (or secondary) SjS.

Systematic literature review

A previous systematic literature review (SLR) reported by the convenor in 2010[7] served to provide SC members with a background to initiate discussions and propose research questions for the SLR focused on the therapeutic management of SjS. On the basis of the research questions, PBZ and SR carried out the SLR between January 1986 and December 2017, with the supervision of the convenor and the methodologists. Summary-of-findings (SoF) tables were generated and levels of evidence (LoE) were determined according to the study design, using the Oxford CEBM standards[17] (online supplementary table S1). The SoFs of the SLR were presented to the SC, whose members formulated a first draft of recommendations based on this information, using electronic and cloud-based working strategies to review the literature search, making comments and maintaining open communication for electronic discussion and amendments. The SLR informing the SC and TF and a detailed description of the methods is published separately. [18] (

Task Force

The TF (online supplementary appendix 1) included 77 specialists in rheumatology, internal medicine, oral health, ophthalmology, gynaecology, dermatology and epidemiology, statisticians, general practitioners, nurses and patient representatives from 30 countries of the five continents (Argentina, Australia, Brazil, Canada, China, Denmark, Egypt, Finland, France, Germany, Greece, Hungary, India, Israel, Italy, Japan, Mexico, Norway, Poland, Portugal, Slovenia, South Korea, Spain, Sweden, Switzerland, the Netherlands, Turkey, the UK and the USA). All TF members declared all potential conflicts of interest. After presentation of the SLR results and the SC proposals to the TF in the first face-to-face meeting, the TF was split into nine breakout working groups (see online supplementary text). Each group proposed draft language and diagnostic/therapeutic algorithms for the respective recommendations to the whole TF. Safety aspects were addressed in each breakout group. Formal economic analyses were not performed, but cost aspects were considered throughout the process. Representatives of each breakout group reported the results of the respective deliberations and presented proposals for the wording of individual recommendations to the whole TF for further discussion and refinement in the second face-to-face meeting.

Consensus findings

After the second meeting, a web-based Delphi procedure was carried out using online voting.[19] The Delphi procedure was designed by MR-C and PB-Z, and developed, managed and analysed by BK using Google Forms; all clinical experts in SjS included in the TF were invited to participate in the Delphi procedure. For an overarching principle or recommendation to be accepted for the final document, TF members were asked to grade for priority according to the level of importance in the daily therapeutic management of SjS (from 1 as unimportant, no priority, no relevance to 5 as very important, a most relevant point, first-order priority); a specific section allowed the inclusion of comments suggested to accompany individual items. Recommendations scoring ≥4 ('important') by >80% of participants were accepted; if this result was not achieved, the respective text was amended and subjected to a second electronic ballot. The approved recommendations were subjected to

Table 1 Overarching (A–C) and specific (1–12) recommendations

	LoE	GoR	Vote (%)	LoA (0–10)
A.Patients with SjS should be managed at, or in close collaboration with, centres of expertise following a multidisciplinary approach	NA	NA	90	9.2
B.The first therapeutic approach for dryness should be symptomatic relief using topical therapies	NA	NA	93	8.9
C.Systemic therapies may be considered for the treatment of active systemic disease	NA	NA	90	9.1
1.Baseline evaluation of salivary gland function is recommended before starting treatment for oral dryness	5	D	81	8.7
2.The preferred first therapeutic approach for oral dryness according to salivary gland function may be:	1a/*1b	B	88	8.7
2.1. Non-pharmacological stimulation for mild dysfunction;				
2.2. Pharmacological stimulation* for moderate dysfunction;				
2.3. Saliva substitution for severe dysfunction				
3.The first-line therapeutic approach to ocular dryness includes the use of artificial tears and ocular gels/ointments	1a	B	98	9.5
4.Refractory/severe ocular dryness may be managed using topical immunosuppressive-containing drops* and autologous serum eye drops	1a/*1b	B/D	94	9.1
5.Concomitant diseases should be evaluated in patients presenting with fatigue/pain, whose severity should be scored using specific tools	5	D	93	9.0
6.Consider analgesics or other pain-modifying agents for musculoskeletal pain, considering the balance between potential benefits and side-effects	4	C	89	8.9
7.Treatment of systemic disease should be tailored to organ-specific severity using the ESSDAI definitions	4	C	89	9.0
8.Glucocorticoids should be used at the minimum dose and length of time necessary to control active systemic disease	4	C	85	9.6
9.Immunosuppressive agents should be mainly used as GC-sparing agents, with no evidence supporting the choice of one agent over another	4	C	82	8.9
10.B-cell targeted therapies may be considered in patients with severe, refractory systemic disease	1b	B	98	8.6
11.The systemic organ-specific therapeutic approach may follow, as a general rule, the sequential (or combined) use of GCs, immunosuppressive agents and biologics	5	D	98	8.6
12.Treatment of B-cell lymphoma should be individualised according to the specific histological subtype and disease stage	4	C	88	9.7

LoE and GoR according to the Oxford Centre for Evidence-based Medicine—LoE (March 2009). Vote (%): % of participants scoring the recommendation as at least 'important' (score of ≥4 on 5-point scale). LoA: mean score (scale of '0' as no agreement, '10' full agreement).
ESSDAI, EULAR Sjögren's syndrome disease activity index; EULAR, European League Against Rheumatism; GC, glucocorticoid; GoR, grade of recommendation; LoA, levels of agreement; LoE, levels of evidence; NA, not applicable.

an anonymous electronic vote on the levels of agreement (LoA). Each recommendation was adjudicated on a scale of 0–10 (0, no agreement; 10, full agreement).

The draft of the manuscript was written by MR-C and PB-Z and was sent to TF members for comment and, after incorporating these comments, to the EULAR Executive Committee for review and approval. Final remarks were obtained from members of the TF and the Executive Committee and addressed in the manuscript (all modifications required approval by the SC), which was then submitted with the final approval of the EULAR Executive Committee after being presented in the EULAR 2019 meeting.[20]

RESULTS

General recommendations

As in other EULAR recommendations, the TF endorsed the presentation of general principles for the management of patients with SjS as overarching, general consensus-based recommendations, since the contents were so generic that there was no requirement to base them on the SLR (table 1).

Patients with SjS should be managed at, or in close collaboration with, centres of expertise using a multidisciplinary approach(*LoE na; LoA 9.2*)

SjS may be a serious systemic disease, not only due to the heavy impact on the health-related quality of live (HRQoL) of the predominant symptoms (the triplet of dryness, fatigue and pain), but also due to the involvement of internal organs (systemic involvement) and the excess mortality caused by cancer (lymphoma). The low frequency of SjS in the general population, combined with a heterogeneous glandular/systemic clinical expression, makes it difficult to ensure a standardised depth of expertise in managing the disease in non-specialised clinical settings. Therefore, we recommend organising SjS management in and around centres of expertise, including professionals with solid clinical experience in assessing patients with SAD. Assessment of SjS patients requires expert guidance, not only to confirm the diagnosis by ruling out non-autoimmune aetiologies (especially for sicca symptoms), but also to evaluate the extent of organs damaged and to design a specific personalised follow-up according to the clinical and biological patient phenotype at diagnosis.[21] A multidisciplinary approach involving various health professionals is essential, with a central role for specialists in autoimmune diseases, who should act as the coordinator of diagnostic and therapeutic healthcare processes, based on a shared-decision policy between the patient and the specialist. The involvement of primary care physicians and other health professionals is highly recommended in the management of SjS patients.

The first therapeutic approach to dryness should be symptomatic relief using topical therapies (*LoE na; LoA 8.9*)

More than 95% of SjS patients present with sicca symptoms,[22] which have a significant impact on the HRQoL.[23–25] Studies that have evaluated the natural history of glandular function in primary SjS (summarised by Haldorsen *et al*)[26] report that, except in early stages of the disease, dysfunction may remain stable for long periods of time (up to 12 years) and have a chronic course, and no study has demonstrated that any therapeutic intervention can reverse glandular dysfunction and, therefore, can cure sicca symptoms. Since the complete disappearance of dryness, which is the desired target for all patients,

Table 2 Glossary and definitions

Term	Definition	Examples
1.Nomenclature of therapies 1.1. Topical therapies 1.2. Systemic therapies	1.1. Interventions directly applied to the mucosal surfaces involved 1.2. Drugs administered orally or intravenously for systemic disease	1.1. Saliva substitutes, ocular tears 1.2. Antimalarials, glucocorticoids, immunosuppressive agents, intravenous immunoglobulins, biologics
2.Disease activity terms 2.1. Systemic disease 2.2. Active systemic disease 2.3. Severe systemic disease 2.4. Refractory systemic disease 2.5. Therapeutic response	2.1. Disease involvement that affects or has affected any of the organs/systems included in the clinESSDAI score 2.2. Patients with clinESSDAI score ≥1. 2.3. Patients with ESSDAI score >14, or high activity in any of the ESSDAI domains with a definition of high activity 2.4. Systemic manifestation/s refractory to SOC. 2.5. Decrease of ≥3 points in the global ESSDAI score	2.1. All ESSDAI domains except biological domain 2.2. Systemic activity is classified as low if ESSDAI is 1–4 (if not only due to biological domain), moderate between 5–13 and high ≥14. 2.3. Lymphadenopathy and lymphoma, articular, cutaneous, pulmonary, renal, muscular central and peripheral neurological and haematological domains. 2.4. Due to the diversity of systemic manifestations, SOC (first-line therapeutic approach) has been defined for each systemic manifestation (figure 3) –
3.Ocular dryness 3.1. Refractory 3.2. Severe	3.1. Refractory ocular dryness is defined as not improvement after using the best-available SOC and ruling out other SjS-unrelated processes, 3.2. Severity should be defined after a specific ophthalmological evaluation of corneal damage by ocular scores:	3.1. SOC defined as the maximum use of artificial tears and ointments according to the previous recommendation 3.2. Measurement of the OSS and OSDI ocular scores
4.Recommended instruments of measure 4.1. Salivary gland function 4.2. Corneal damage 4.3. Fatigue 4.4. Pain 4.5. Quality of life 4.6. Systemic disease	4.1. UWSF, SWSF 4.2. OSS, OSDI 4.3. ESSPRI domains, ProFAD 4.4. ESSPRI domains, BPI 4.5. ESSPRI 4.6. ESSDAI, clinESSDAI	
5.Potential life-threatening systemic manifestations	5.1. Cutaneous domain 5.2. Pulmonary domain 5.3. Renal domain 5.4. Muscular domain 5.5. Peripheral nerve system domain 5.6. CNS domain 5.7. Haematological domain	5.1. Diffuse vasculitis with ulcers 5.2. ILD with NHYA III/IV 5.3. Renal failure; rapidly-progressive glomerulonephritis; hypokalaemic paralysis 5.4. Muscular involvement with severe weakness 5.5. Neuropathy (including ganglionopathy and polyradiculopathies) with severe motor deficit/ataxia; cryoglobulinemic-related multineuritis 5.6. Demyelinating disease with motor deficit; cerebral vasculitis presenting with focal deficit; myelitis; meningoencephalitis 5.7. Severe haemolytic anaemia (<80 g/dL, <50 x109/L); severe autoimmune thrombocytopenia (<50 000/mm3)

BPI, brief pain inventory; CHB, congenital heart block; CIDP, chronic inflammatory demyelinating polyradiculopathy; CNS, central nervous system; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index; ESSPRI, EULAR Sjögren's Syndrome Patient Reported Index; EULAR, European League Against Rheumatism; G-CSF, granulocyte colony-stimulating factor; ILD, interstitial lung disease; KCS, keratoconjunctivitis sicca; LIP, lymphoid interstitial pneumonitis; MMF, mycophenolate mofetil; MP, methylpredisolone; MS, multiple sclerosis; NAC, N-acetylcysteine; NHYA, New York Heart Association; NMOSD, neuromyelitis optica spectrum disorder; NSIP, non-specific interstitial pneumonitis; OP, organising pneumonitis; OSDI, Ocular Surface Disease Index; OSS, Ocular Staining Score; PN, peripheral neuropathy; ROR, retinoic acid-related orphan receptor; RTX, rituximab; SjS, Sjögren syndrome; SOC, standard of care; STAT, signal transducer and activator of transcriptionm; SWSF, stimulated whole salivary flows; TOR, mammalian target of rapamycin; UIP, usual interstitial pneumonitis; UWSF, unstimulated whole salivary flows.

is at present unreachable, the TF recommends exploring the use of other, more realistic outcomes, such as the minimal clinically-important improvement or the patient-acceptable symptom state, following the corresponding ESSPRI definitions,[13] always closely aligned with patient education, including coping strategies. The chronic course of SjS means a daily, long-term use of therapies and, in this scenario, it is reasonable to recommend the use of therapies with a minimum of (or at least tolerable and reversible) side effects. This is overwhelmingly fulfilled by topical therapies (see definition in table 2). Various studies and Cochrane SLRs support the daily use of topical therapies for the symptomatic relief of dryness, with a significant improvement in HRQoL without significant side effects.[7 27 28] These therapies should be immediately initiated after objective confirmation of glandular dysfunction.

Systemic therapies may be considered for the treatment of active systemic disease (*LoE na; LoA 9.1*)

Systemic disease is a key prognostic determinant of SjS and is linked to autoimmune-mediated organ/s dysfunction that may eventually become irreversible. The use of systemic immunomodulatory/immunosuppressive therapies (glucocorticoids (GCs), antimalarials, immunosuppressive agents, intravenous immunoglobulins and biologics) should be restricted to patients with active systemic disease (see definition in table 2) but only after a careful organ-by-organ evaluation of both severity and organ damage, since not all patients with active systemic disease will necessarily require systemic therapy (this was why the original wording using 'should be' was changed to 'may be'). As a general rule, the management of systemic features in SjS should follow a schedule consisting of a two-stage sequential regimen as used in other SAD, including a first intensive immunosuppressive approach targeted to restore organ function (induction of remission) as soon as possible, followed by a second therapeutic course aimed at maintaining the initial therapeutic response (maintenance of remission). Unfortunately, there are no available data in patients with SjS to support specific recommendations on the need for/duration of induction and maintenance therapies, which should therefore be decided on case-by-case.

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

Specific recommendations

The 12 specific recommendations form a logical sequence, starting with the management of the central triplet of symptoms (dryness, fatigue and pain) followed by the management of systemic, extraglandular disease (table 1).

Baseline evaluation of salivary gland function is recommended before starting treatment for oral dryness (*LoE 5, LoA 8.7*)

The therapeutic approach to oral dryness should be driven by the baseline measurement of salivary glandular function, and not by the patient's subjective feelings, since environmental and personal stressing factors may influence the subjective feeling of dryness,[29] which often does not match with the objective measurement of glandular function. We recommend the baseline evaluation of salivary glandular function by measuring whole salivary flows before starting therapeutic interventions, always ruling out SjS-unrelated conditions (ie, candidiasis, burning mouth syndrome); salivary scintigraphy may also be considered.[30] This item elicited significant discussions about the specific tests for measuring glandular function (unstimulated whole salivary flows and stimulated whole salivary flows (SWSF), and salivary scintigraphy), especially the use of SWSF and salivary scintigraphy, which were considered as complicated tests in daily practice by several TF members, and not always available in all clinical settings.

The preferred first therapeutic approach for oral dryness according to salivary gland function may be: Non-pharmacological stimulation for mild dysfunction; pharmacological stimulation for moderate dysfunction*; saliva substitution for severe dysfunction (*LoE 1a/*1b, LoA 8.7*)

On the basis of the results obtained in the measurement of salivary gland function, the therapeutic approach to oral dryness may be initiated based on two mechanisms: salivary gland stimulation (non-pharmacological or pharmacological) or saliva substitution (figure 1).[31]

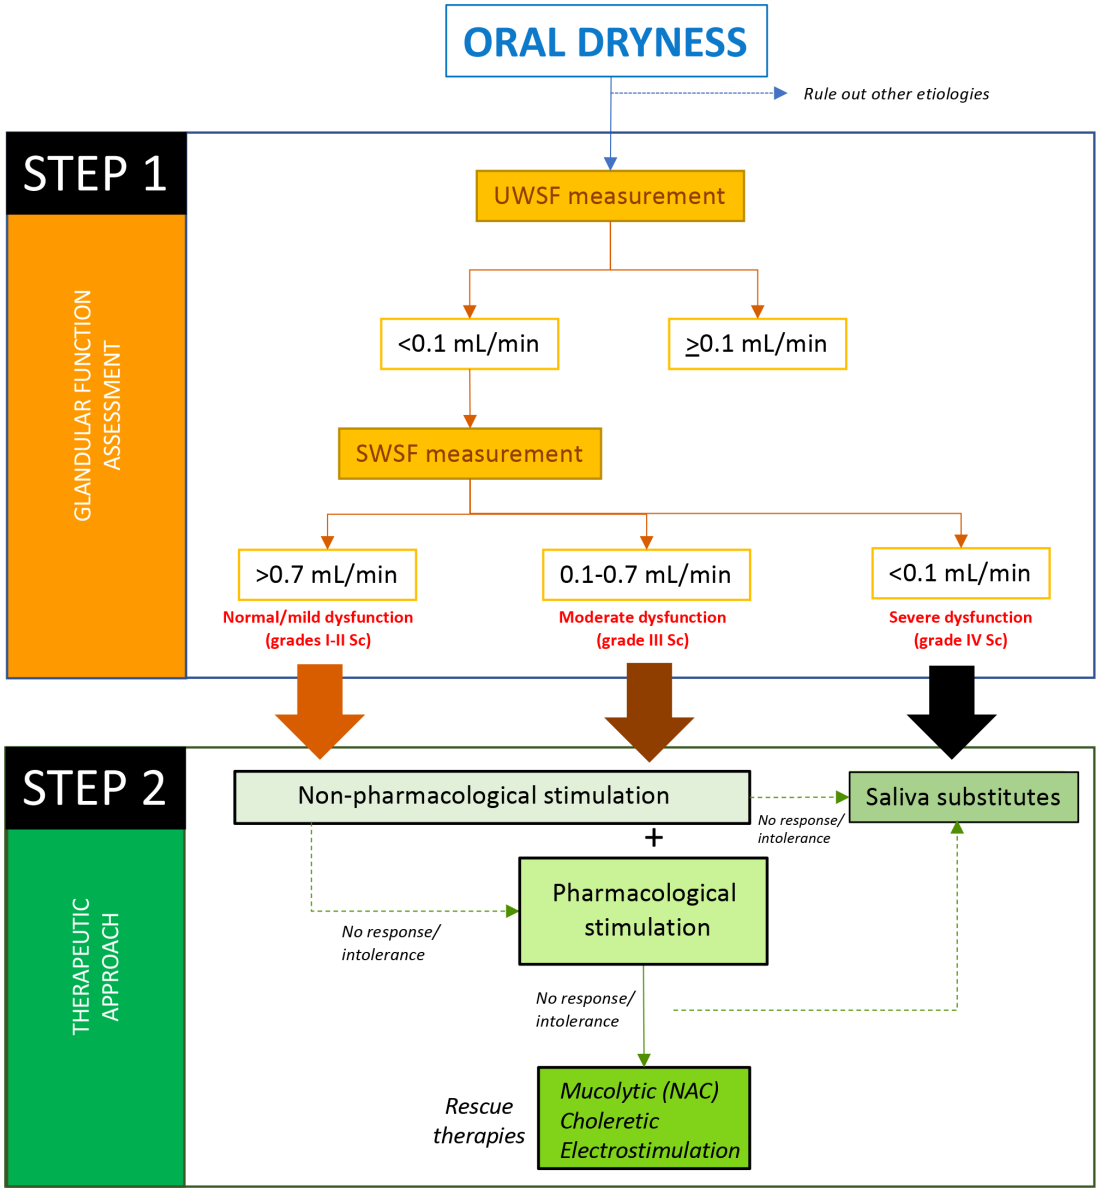

Figure 1 Algorithm of glandular function assessment and therapeutic approach in patients with primary SjS presenting with oral dryness. SjS, Sjögren syndrome; SWSF, stimulated whole salivary flows; UWSF, unstimulated whole salivary flows.

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

Non-pharmacological stimulation

In patients with mild glandular dysfunction, we recommend non-pharmacological glandular stimulation as the preferred first-line therapeutic approach, using gustatory stimulants (sugar-free acidic candies, lozenges, xylitol) and/or mechanical stimulants (sugar-free chewing gum) since, in these patients, glandular function can be stimulated (figure 1). With no evidence available for pSjS-2002 patients, evidence was extrapolated from a Cochrane SLR[27] focussed on the therapeutic management of oral dryness; the authors concluded that all non-pharmacological interventions evaluated relieve subjective symptoms to some, unquantified degree, without strong evidence that any intervention was more effective than another, although no study evaluated the therapeutic response according to the degree of salivary gland dysfunction.[27]

Pharmacological stimulation

In patients with moderate glandular dysfunction, pharmacological stimulation with muscarinic agonists may be considered. Two drugs (pilocarpine and cevimeline) are licensed for the treatment of oral dryness, although only pilocarpine is licensed worldwide. The three pivotal randomised controlled trials (RCTs) included both primary and associated SjS patients fulfilling the 1993 criteria, and found significant improvements in visual analogue scale (VAS) dry mouth and salivary flow rates, with a high frequency of adverse events.[7] The available evidence in pSjS-2002 patients is limited to one small prospective study using pilocarpine that found improvement in subjective but not objective oral outcomes,[32] and a second study with no detailed information about overall efficacy and safety.[33] A third retrospective study which compares pilocarpine and cevimeline, only focussed on the safety profile,[34] and reported a better tolerance profile for cevimeline. The evidence is too limited to make a strong recommendation for pSjS-2002 patients (the best level of evidence should be extrapolated from RCTs including patients fulfilling the former 1993 criteria). For this reason, and together with the unfavourable safety profile of these drugs, we recommend offering a trial of muscarinic agonists to patients with moderate glandular dysfunction (or in those with mild dysfunction who are refractory or who do not wish to use non-pharmacological stimulation) (LoE 1b, GoR B) (figure 1). To reduce the main side effect (excess sweating), and based on clinical practice, some TF experts recommended increasing the dose progressively up to 15 to 20 mg/day when possible. In patients who are intolerant or non-responders to muscarinic agents, some choleretic (anetholtrithione) or mucolytic (bromhexine, N-acetylcysteine) agents used as secretagogues in SjS since the 1980s may be considered as rescue therapies due to their good safety profile in the absence of alternative therapeutic options, and taking into account the limitations of the study design and the marginal benefits reported by most studies.[7] According to the SLR results, for the treatment of oral dryness we do not recommend the use of hydroxychloroquine (no placebo-differences for subjective and objective oral outcomes in the pivotal RCT), oral GCs, immunosuppressive agents (overwhelmingly-negative results with excess side effects) or rituximab (no placebo-differences for subjective and objective oral outcomes in the two pivotal RCT and one meta-analysis)

Saliva substitution

Saliva substitution should be considered the preferred therapeutic approach to alleviate symptoms in patients with no residual glandular function (severe glandular dysfunction), in whom salivary glands cannot be stimulated, either by pharmacological or non-pharmacological interventions (figure 1). The ideal preparation will have a neutral pH and contain fluoride and other electrolytes, mimicking the composition of natural saliva; saliva substitutes are available commercially in the form of oral sprays, gels and rinses.[10] Only one prospective study evaluated pSjS-2002 patients[35] and found no statistically-significant placebo-differences for the primary outcome, although significant improvements were reported in some subjective oral outcomes, with no side effects reported. Evidence can be extrapolated from a Cochrane SLR that evaluated the effectiveness of topical treatments for any-cause dry mouth; the review found no superiority for any therapeutic option.[27] In spite of the limited evidence available, we recommend their use in the target population because, in the experience of TF members, patients often report increased oral comfort without significant side effects.[10] Oral gel-like formulations may be useful in patients with an acceptable salivary flow output, particularly when they complain about nocturnal oral dryness, although these patients often have a poor tolerance to saliva substitutes due to the sticky feeling caused by their application, which may be reduced by diluting the saliva substitute. Pretherapeutic evaluation of salivary function may also aid the choice of a specific formulation of saliva substitutes (gel, saliva substitute—diluted or not,mouth rinses), with less thick/dense preparations being preferred for patients with a better-preserved glandular function.[36] The preferred first-line use of saliva substitutes in patients with no salivary output elicited an intense debate within the TF, probably due to the apparent paradox of using a topical therapy in patients with severe glandular involvement. Several TF members expressed a dissenting view, stating that saliva substitutes should be used in all patients with oral dryness, irrespective of glandular function. Whether or not a saliva substitute is used, a neutral pH sodium fluoride gel should be prescribed to all patients with severe salivary dysfunction to prevent rampant caries.

The first-line therapeutic approach to ocular dryness includes artificial tears and ocular gels/ointments (*LoE 1a, LoA 9.5*)

The first line of therapy for ocular dryness should be volume replacement and lubrication using artificial tears (AT) and ocular gels, whose main ingredients are lubricants with a polymeric base or viscosity agent (methylcellulose, hyaluronate) with the aim of adding volume to the tear lake, increasing the time the AT remain on the ocular surface, and cushioning the ocular surface to reduce friction between lid and globe.[37] All SjS studies testing AT (only one in pSjS-2002 patients) found significant improvements for both subjective and objective ocular outcomes, while a recent Cochrane review on the use of AT for dry eye syndrome showed that they are safe and effective.[28] We recommend that all SjS patients presenting with ocular dryness and/or abnormal ocular tests should use AT containing methylcellulose or hyaluronate at least twice daily, with the frequency increased to as often as hourly, as indicated by symptoms and/or objective signs. The use of preservative-free formulations of AT is mainly recommended in patients requiring four or more applications per day. Ophthalmic ointments are thicker than AT and may be used to provide symptom control overnight; they are typically used before bedtime because they produce blurred vision and their use should be followed by morning lid hygiene to prevent blepharitis.[37]

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

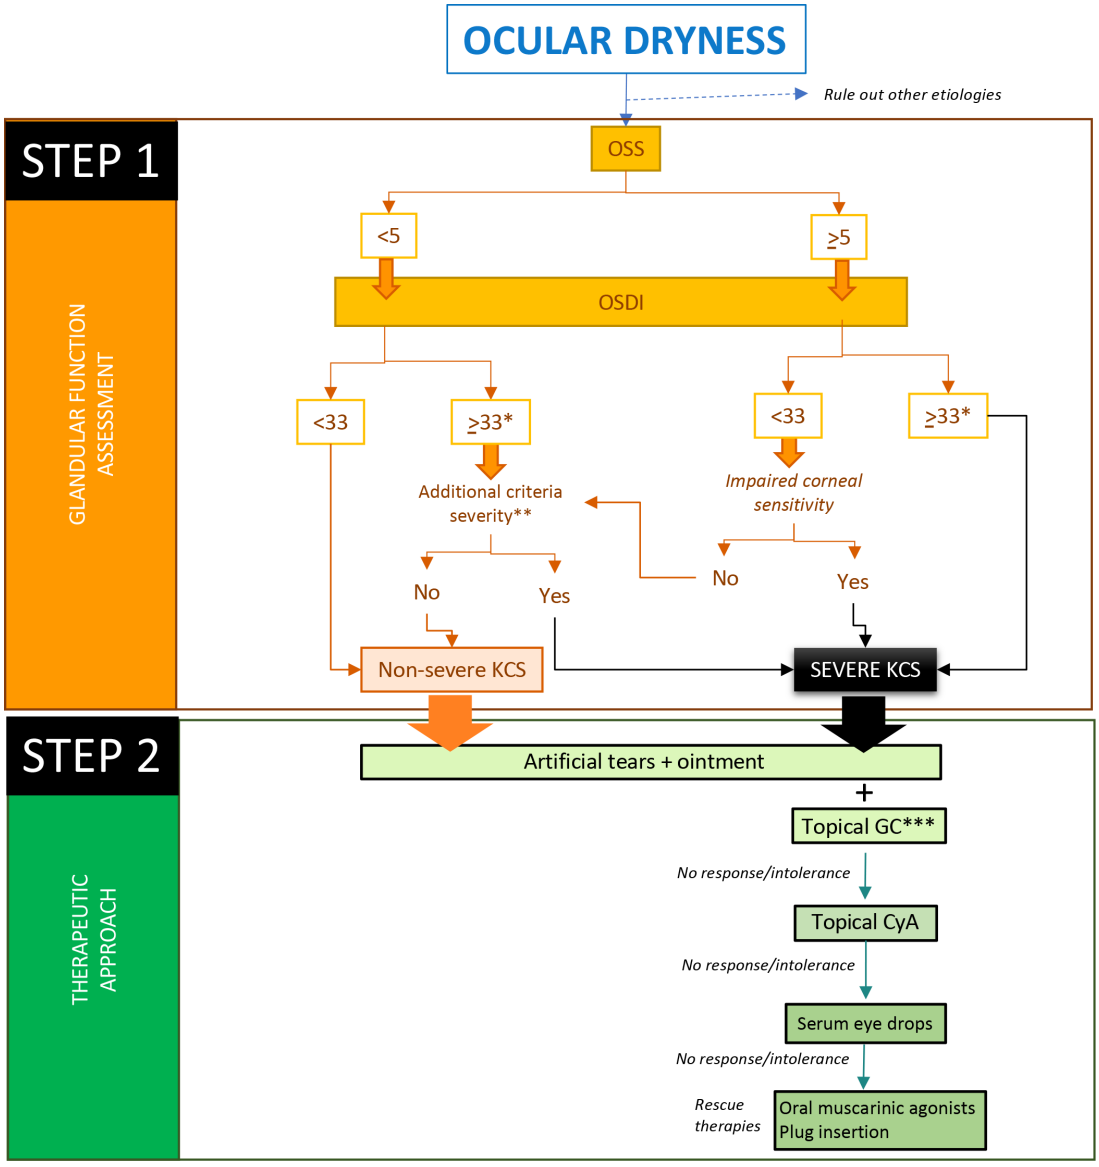

Figure 2 Algorithm of glandular function assessment and therapeutic approach in patients with primary SjS presenting with ocular dryness. *Consider neuropathic pain if OSS≤1. **Additional criteria for severity: (1) impaired visual function (photophobia, visual acuity modification or low contrast sensitivity); (2) blepharospasm (secondary to ocular inflammation); (3) severe meibomian gland disease or eyelid inflammation. ***For short-term indications (2–4 weeks). CyA, ciclosporin A; GC, glucocorticoid; OSS, ocular staining score (Whitcher[107] JP, *et al*. Am J Ophthalmol. 2010;149:405–15). OSDI, ocular surface disease index (adapted from Baudouin C,[108] *et al*. Br J Ophthalmol 2014;98:1168–1176); SjS, Sjögren syndrome.

Refractory/severe ocular dryness may be managed using topical immunosuppressive-containing drops* and serum eye drops (*LoE 1a/*1b, LoA 9.1*)

Patients with refractory or severe ocular dryness should be managed by an ophthalmologist with substantial experience in corneal disease wherever possible. Refractory ocular dryness is defined as patients who do not improve after using the best-available standard of care (SOC) (defined as the maximum use of AT and ointments according to the previous recommendation) after ruling out other SjS-unrelated ocular processes (ie, blepharitis), while severity should be defined according to the results obtained in a specific ophthalmological evaluation of corneal damage by measuring the OSS, together with patient symptoms as assessed by the Ocular Surface Disease Index (figure 2).

Topical NSAIDs/corticosteroids

Topical ocular non-steroidal anti-inflammatory drugs (NSAIDs) or corticosteroids may be prescribed by ophthalmologists as a short-term therapeutic approach (maximum 2–4 weeks), as adverse events may occur with continued use of topical NSAIDs (corneal–scleral melts, perforation, ulceration and severe keratopathy) or topical corticosteroids (infections, increased intraocular pressure and worsening/development of cataracts).[37] Evidence in pSjS-2002 patients is limited to one small case-control study[38] using topical fluorometholone which found no significant differences in comparison with topical ocular ciclosporin A (CyA).

Topical CyA

In December 2002, an ophthalmic formulation containing 0.05% CyA was approved by the Food and Drug Administration to treat dry eye disease in the USA based on the results of two RCTs including patients with keratoconjunctivitis sicca (SjS patients were included in variable proportions).[7] There are no specific RCTs carried out in pSjS-2002,[39 40] and only one recent case-control study, which reported no significant differences

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

between groups in comparison with topical fluorometholone, with a higher frequency of moderate-to-severe transient burning sensation in patients receiving CyA.[38] Ophthalmologists may consider the use of ocular CyA drops in patients with refractory or severe ocular dryness requiring repeated courses of glucocorticoid tear drops. The promising results of a recent small trial using tacrolimus tear drops[41] required further confirmation in large trials.

Serum tear drops

In SjS patients, the role of autologous or allogenic serum has been tested in small uncontrolled studies showing inconsistent benefits (no improvement in all objective ocular outcomes evaluated). A recent Cochrane SLR on the use of serum tear drops for dry eye syndrome[42] has confirmed inconsistencies in their possible benefits both for symptoms and objective measures, with no evidence of an effect after 2 weeks of treatment. Only one study has been carried out in pSjS-2002 patients, which showed significant improvement in some ocular outcomes.[43] The difficulties in preparation, the need to refrigerate the drops, and the potential risk of contamination should be taken into account.[37 44] The TF recommended that serum tear drops may be considered in patients who are non-responders or intolerant to topical CyA tear drops.

Rescue therapies

Other therapeutic interventions may be considered after failure of the above-mentioned therapies, including topical and systemic therapies. A recent Cochrane SLR reviewing the use of plugs for dry eye syndrome[45] found that the evidence was very limited, and concluded that improvements in subjective and objective ocular outcomes were inconclusive. Two studies have been carried out in primary-2002 SjS patients: the first found no significant differences between groups (insertion of plugs vs AT),[46] and the second reported improvement in only two of four ocular outcomes evaluated.[47] With respect to systemic therapies, oral muscarinic agonists may be considered on the basis of the improvement of subjective (not objective) ocular outcomes.[7] According to the SLR results, for the treatment of ocular dryness we do not recommend the use of hydroxychloroquine (no placebo-differences for subjective and objective ocular outcomes in the pivotal RCT), immunosuppressive agents (overwhelmingly negative results with excess side effects) or rituximab (no placebo-differences for subjective and objective oral outcomes in the two pivotal RCT and one meta-analysis).

In summary, although patients with refractory/severe ocular dryness may require a more intensive ophthalmological follow-up and, probably, more complex therapies, including immunosuppressive-based tear drops (topical corticosteroids or CyA) and serum tear drops, the low level of current evidence for the use of these complex ophthalmological therapies in primary SjS-2002 patients do not permit the TF to establish a strong preference among the options. The expertise of the ophthalmologist and the specific characteristics of the patient will drive both the preferred first-line therapy and the sequential use of the therapeutic interventions.

Concomitant diseases should be evaluated in patients presenting with fatigue/pain, whose severity should be scored using specific tools (*LoE 5, LoA 9.0*)

Patients with primary SjS often present with general symptoms, of which most frequent are non-inflammatory joint/muscle pain and fatigue/weakness, which may have a much greater impact on the HRQoL than sicca features, as reported in cross-sectional studies.[23–25] Unfortunately, these symptoms are very unspecific and could be related to a wide range of concomitant pathologies (osteoarthritis, hypothyroidism, hypocortisolism, vitamin deficiencies, depression, neoplasia) and even to some systemic complications of systemic SjS (arthritis, anaemia, hypokalaemia, osteomalacia, lymphoma, small-fibre neuropathy). A specific comment is needed on the association between SjS and some somatic functional syndromes such as chronic fatigue syndrome and fibromyalgia, whose peak of incidence occurs in the same population subset as SjS (middle-aged women).[21] No studies have confirmed a solid aetiopathogenic autoimmune link between SjS and chronic fatigue syndrome/fibromyalgia[48] beyond the evident epidemiological overlap. Since the association of these somatic syndromes could heavily influence both the patient and physician global health status evaluation, we recommend searching for these syndromes using standardised recommendations,[49] and measuring the severity of pain and fatigue using specific scales such as the corresponding ESSPRI domains, the Profile of Fatigue (for measuring fatigue) and the Brief Pain Inventory (for measuring pain).[50] SjS patients may describe various kinds of pain and fatigue, and the use of both general and SjS-specific questionnaires will permit not only a standardised measurement of their potential impact on HRQoL, but consideration of their influence when specific therapeutic interventions are initiated.[10 51]

Consider analgesics or other pain-modifying agents for musculoskeletal pain, taking into account the balance between potential benefits and side-effects (*LoE 4, LoA 8.9*)

With respect to SjS-related musculoskeletal pain, a clear pretherapeutic differentiation must be made clinically between joint pain (arthralgia) and joint inflammation (arthritis, tenosynovitis).[52] The ESSDAI score classifies arthralgia in the hands, wrists, ankles and feet accompanied by morning stiffness (>30 min) as low articular activity level, always ruling out concomitant osteoarthritis. Arthritis is clinically diagnosed on the basis of objective inflammation of ≥1 joints (heat, redness and swelling in the physical examination of the affected joint) supported by ultrasound studies when in doubt, and the ESSDAI score classifies the severity of arthritis according to the number of joints involved (moderate ≤5 joints, high >5).[12] The therapeutic management of arthritis is included in the systemic recommendations. (a) In patients presenting with acute musculoskeletal pain, consider acetaminophen or NSAIDs for symptomatic relief, always for less than 7–10 consecutive days at full dosage and considering the side effects and underlying comorbid diseases. In real life, a large retrospective study in 188 primary 2002 SjS patients with joint involvement reported that nearly one third had a rapid clinical response to the short-term use of analgesics/NSAIDs.[53] Topical formulations of NSAIDs (topical diclofenac or ketoprofen) may be effective for local pain with fewer side effects,[54] but there is no available evidence in SjS patients.[55] (b) In patients with frequent episodes of acute musculoskeletal pain, the use of hydroxychloroquine has been proposed based on its comparable use in other SAD such as systemic lupus erythematosus (SLE). Although uncontrolled studies have reported improvement in joint pain, the pivotal RCT failed to demonstrate that hydroxychloroquine improved pain after 24 weeks of treatment in comparison with placebo, although a statistical trend was reported (p values between 0.06 and 0.10) at 12, 24 and 48 weeks).[56] Taking this positive trend, the lack of reported cases of retinal toxicity or severe adverse events, and the lack of pharmaceutical

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

alternatives with a similar indication/safety profile, the TF members agreed to consider the use of hydroxychloroquine in some patients with frequent episodes of articular pain. In real life, the study by Fauchais *et al*[53] reported the use of hydroxychloroquine in more than half the patients presenting with joint involvement. With respect to the use of biological agents to treat these symptoms, the data from the two pivotal RCTs[57 58] on the effect of rituximab on pain and fatigue reported no significant differences in comparison with placebo for both pain and fatigue VAS (although some differences were found at intermediate evaluation points in the French study), together with no significant placebo-differences in quality-adjusted life-year but with a fivefold greater economic cost,[58] while a recent meta-analysis[59] confirmed no significant differences after combining the results of these trials. In addition, a small RCT using anakinra found no significant reduction in fatigue in its primary endpoint,[60] while the promising results obtained in two small open-label studies (<30 patients) using epratuzumab[61] or abatacept[62] must be confirmed in further large RCTs. Therefore, we consider that the off-label use of biological agents to treat only musculoskeletal pain (even as rescue therapy) is not currently warranted. (c) In patients with chronic, daily non-inflammatory pain, the management must be completely different, avoiding the repeated use of NSAIDs or GCs. The non-pharmacological management of pain should be emphasised, instead of going straight to prescribing medications for the symptoms. Therefore, the first therapeutic step should be to follow the same recommendations as those proposed for general chronic pain, by suggesting that physical activity and aerobic exercise are interventions with few adverse events that may reduce pain severity and improve physical function.[63] In addition, a small case-control study in primary SjS patients showed significant improvement in aerobic capacity, fatigue and ratings of perceived exertion and depression in patients allocated to the exercise group.[64] Antidepressants and anticonvulsants may be considered for chronic musculoskeletal pain, while patients with chronic neuropathic pain may require the use of gabapentin, pregabalin or amitriptyline (paying attention to potential exacerbations of dryness symptoms). Recent epidemiological data confirm that opioids must not be used.[65]

Treatment of systemic disease should be tailored to organ-specific severity using the ESSDAI definitions (*LoE 4, LoA 9.0*)

In non-specialised medical settings, primary SjS is often considered a chronic, non-life-threatening disease that only causes dryness, fatigue and pain. However, systemic involvement has been increasingly recognised as a key part of the disease, with a significant weight in dictating the prognosis and survival in retrospective studies.[66–69] The development of the ESSDAI by the EULAR-SS Task Force Group has provided a helpful, objective instrument to measure systemic involvement in primary SjS that is accepted worldwide. According to overarching principle C, we recommend that the use of systemic therapies (GCs, antimalarials, immunosuppressive agents, intravenous immunoglobulins, biologics) should be restricted to patients with active systemic disease (see definitions in table 2). However, the management of systemic features must be tailored to the specific organ involved and the severity evaluated by the ESSDAI.[69] As an overall rule, systemic therapies may be considered for most patients presenting with at least moderate activity in one clinical domain, or with a global moderate disease activity score (score ≥5). With respect to the definition of the therapeutic response in systemic SjS, the TF recommends using a reduction of ≥3 points in the global ESSDAI score.[70] It should also be considered that some systemic manifestations are not captured by the ESSDAI, including Ro-associated congenital heart block, Raynaud phenomenon, primary pulmonary hypertension, pleuritis, pericarditis, dysautonomia, interstitial cystitis and sensorineuronal hearing loss; these features require specific patient-by-patient management.

GCs should be used at the minimum dose and length of time necessary to control active systemic disease (*LoE 4, LoA 9.6*)

The frequent use of GCs in clinical practice in primary SjS patients[69 71 72] is not supported by reliable scientific evidence, since no controlled study has specifically evaluated their use for systemic disease. Available data come mainly from retrospective studies (online supplementary table S2) and case series/reports, which also highlighted the high rate of GC-related adverse events. We recommend that GCs should be used at the minimum dose and length of time necessary to control active systemic disease, administering pulses of methylprednisolone followed by doses of 0.5 mg/kg/d or lower as induction therapy in severe presentations (table 2), and doses<0.5 mg/kg/d in moderate/less-severe presentations, with a final target of withdrawing GCs in inactive patients as soon as possible or at least trying to target a maintenance dose of 5 mg/daily or less with the aid of GC-sparing immunosuppressive agents (see recommendation 'Synthetic immunosuppressive agents should mainly be used as GC-sparing agents, with no evidence supporting the choice of one agent over another (*LoE 4, LoA 8.9*)'). No available data in SjS patients support specific recommendations on the rate of de-escalation of the GC dose, or when a GC-sparing agent should be added, or the length of GC therapy, although we recommend tapering GCs as rapidly as clinically feasible. We recommend to follow the EULAR evidence-based and consensus-based recommendations on the management of medium to high-dose glucocorticoid therapy in rheumatic diseases.[73]

Synthetic immunosuppressive agents should mainly be used as GC-sparing agents, with no evidence supporting the choice of one agent over another (*LoE 4, LoA 8.9*)

Based on the potential development of chronic damage in patients with uncontrolled systemic disease, some patients may require long-term therapy with GCs, especially those with severe organ impairments.[69 71 72] In these patients, the addition of immunosuppressive agents as GC-sparing agents is justified, always weighing the potential benefits and risks. The use of immunosuppressive agents in primary SjS is based on the same level of evidence as that of GCs, since all reported studies (prospective uncontrolled studies, all including less than 50 patients) were principally centred on the efficacy in sicca features and laboratory parameters, but not on the efficacy in systemic disease, with an unacceptable rate of adverse events (ranging between 41% and 100%).[7] The lack of head-to-head studies comparing the efficacy and safety profile of immunosuppressive agents in primary SjS-2002 (leflunomide, methotrexate, azathioprine, mycophenolate, cyclophosphamide) does not permit a recommendation on the use of one agent over another, except when patient characteristics or comorbidities are considered with respect to the safety profile. In addition, there is no information available about the dose, route of administration and length of treatment and we recommend a case-by-case evaluation following similar rules to those reported for other SAD. Although some TF members suggested the use of monotherapy with immunosuppressive agents, there was no final consensus on this option due to the lack of studies demonstrating the efficacy

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

of GC-free regimens in SjS, and the fact that more than 95% of reported cases using immunosuppressive agents in primary SjS-2002 received associated GCs (online supplementary table S2). Several immunomodulatory agents have been tested in SS, with marginal benefits or with an unacceptable rate of adverse events and are not recommended.[7]

B-cell targeted therapies may be considered in patients with severe, refractory systemic disease (*LoE 1b, LoA 8.6*)

The emergence of biological therapies in this century has increased the therapeutic armamentarium available for treating severe SjS. These new drugs have the highest level of evidence among all the drugs tested for SjS, not only because have they have been tested in a large number of patients (>1000), but also because most of reported RCTs in primary SjS have tested biologics. Unfortunately, their use in clinical practice is clearly limited by the lack of licensing. B-cell targeted therapies are the most frequently tested biological drugs, and include epratuzumab[61] and belimumab,[74 75] although the most widely studied B-cell target therapy is rituximab.[57 58 76–86]

Studies with available data on the efficacy of rituximab on systemic involvement have included more than 400 patients with primary SjS-2002 (online supplementary table S3), with a predominant use of the regimen of 2 doses of 1 g each administered 15 days apart.[7] Four main systemic outcomes were evaluated at different follow-up times in these studies: the global therapeutic response, organ-specific response, change in the global ESSDAI score and reduction in prednisone use. Uncontrolled studies have reported a global response rate of 60%–100% for systemic features, especially cryoglobulinemic features.[76 77 79 80 86] One small RCT[86] reported a significant reduction in reported extraglandular manifestations and improvement of musculoskeletal features at weeks 12 and 36 (p=0.029) and vasculitis at week 24 (p=0.03). Four studies (two retrospective, one case-control and one prospective) have reported a statistically-significant reduction in the global baseline ESSDAI score (from 9 to 20.3 to 2.5–5.2 after treatment).[77–80 84] In the two pivotal RCTs, Devauchelle *et al* found no differences in the mean ESSDAI improvement,[57] while Bowman *et al*[58] reported statistically-significant placebo differences at week 36 (p=0.03) and a statistically-significant trend at week 48 (p=0.07) in the log-transformed ESSDAI score. Three retrospective studies have demonstrated a statistically significant reduction in the daily dose of GCs.[76 79 80] In summary, the great majority of studies showed efficacy in at least one of the systemic outcomes analysed (global response, organ-specific response, ESSDAI reduction, prednisone reduction).

The results of the Efficacy and Safety of Belimumab in Subjects with Primary Sjögren's Syndrome open label trial[74] in 30 pSjS-2002 patients treated with belimumab showed a reduction in the mean ESSDAI score from 8.7 to 5.7 at week 28 (p<0.0001), with a decrease of at least 4 points in 40% of cases and improvements in

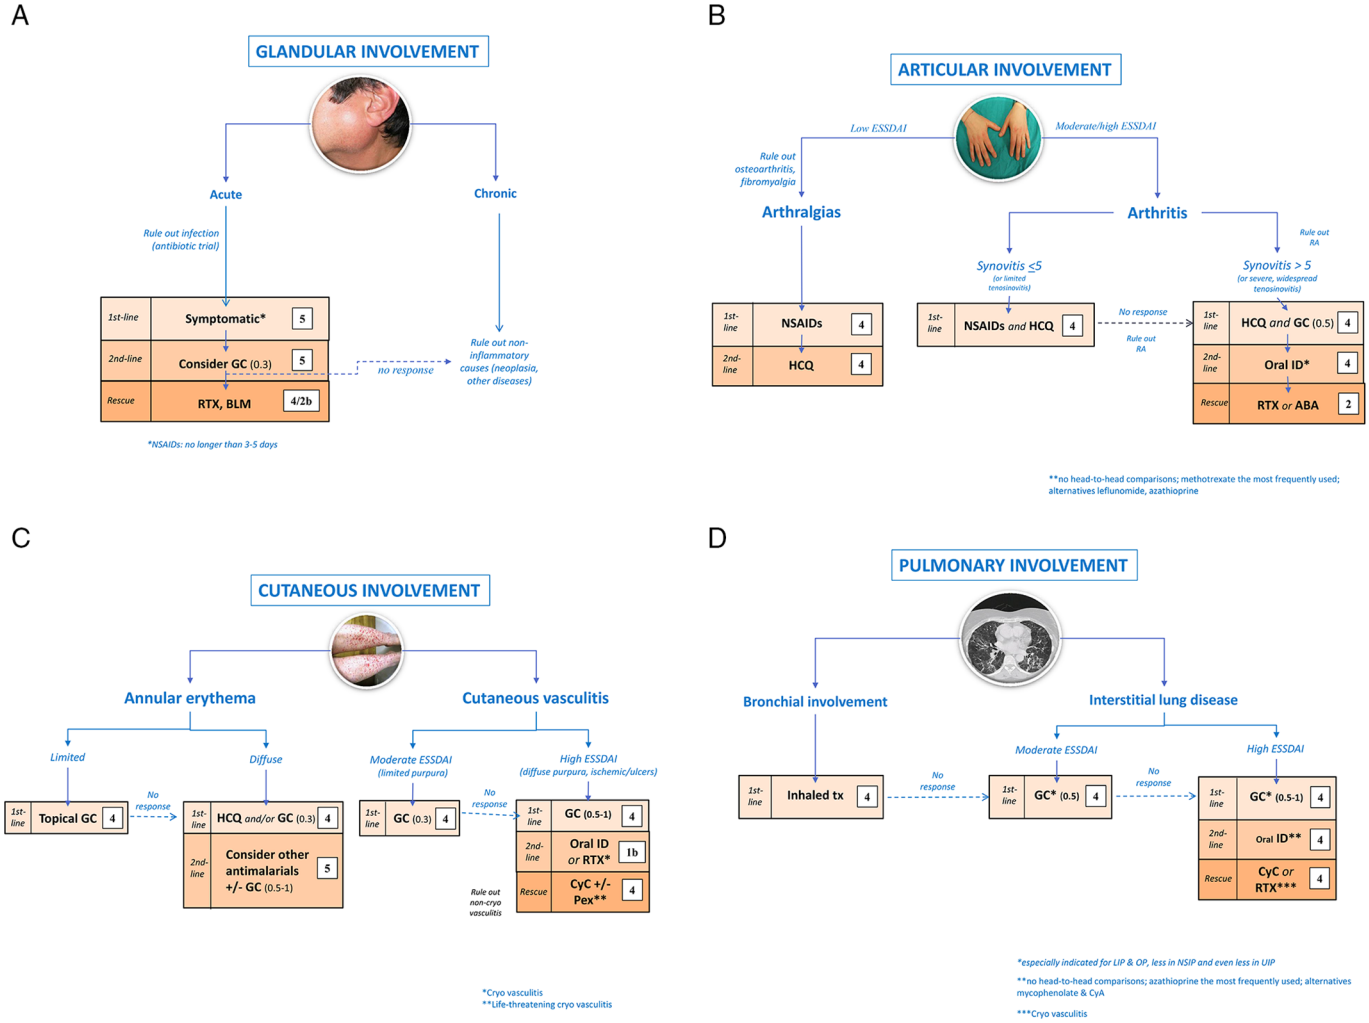

Figure 3 *(Continued)*

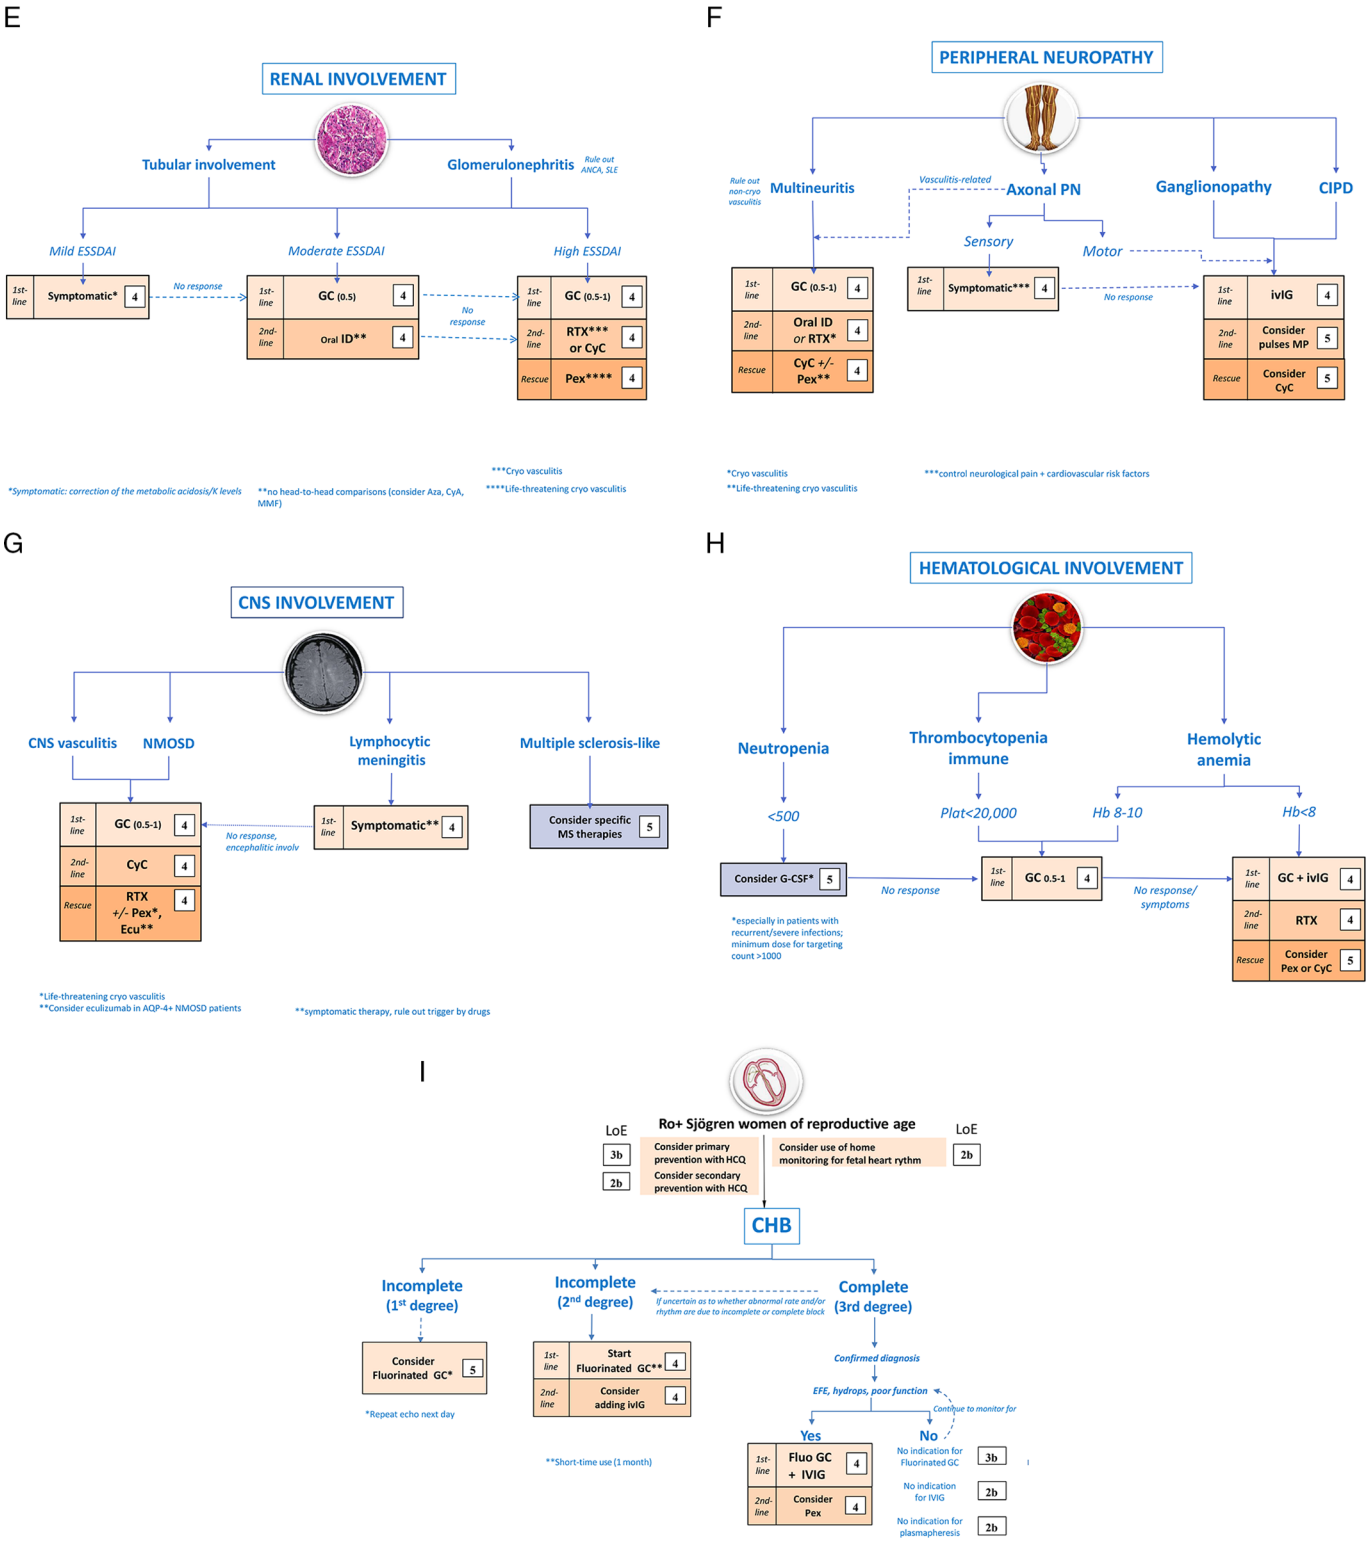

Figure 3 (A to I) Algorithm for the therapeutic approach to patients with primary SjS presenting with organ-specific systemic involvements. NSAIDs: no longer than 7–10 days. HCQ: hydroxychloroquine 200 mg/day. GC (recommended dose in mg/kg/day); short-term course whenever possible; consider methylprednisolone pulses in severe cases. ID: immunosuppressive agents, no head-to-head comparisons. CyC: cyclophosphamide pulses 0.5 g/15 day (maximum six pulses). Rituximab: rituximab 1 g/15 days (x2). BLM: belimumab; 10 mg/kg (0, 2 and 4 weeks and then every 4 weeks). ABA: abatacept 0, 2, 4 weeks and every 4 weeks. IVIg: intravenous immunoglobulins 0.4–2 g/kg 5 days. PEX: plasma exchanges. CyA, ciclosporin A; EULAR, European League Against Rheumatism; ESSDAI, EULAR Sjögren's syndrome disease activity index; GC, glucocorticoid; LoE, levels of evidence; NSAIDs, non-steroidal anti-inflammatory drugs; RA, rheumatoid arthritis; SjS, Sjögren syndrome.

parotid swelling in 77% of cases; of five patients previously refractory to rituximab, belimumab was effective in 3 (60%). In a study extension of the 19 patients that completed 1 year of treatment, a significant improvement was maintained.[75] With respect to the safety profile, one severe adverse event was reported (pneumococcal meningitis) after 6 infusions of belimumab.

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

After intense discussion among the TF members and balancing the positive results of uncontrolled studies, the weak evidence reported by RCTs, and the fact that the trials were not primarily designed to evaluate the systemic response, we agreed that the use of rituximab may be considered (we changed the original wording of 'should be') in patients with severe, refractory systemic disease, and that the best indication is probably for symptoms linked to cryoglobulinemic-associated vasculitis,[87] with the possible use of belimumab as rescue therapy.

The systemic organ-specific therapeutic approach may, as a general rule, follow the sequential (or combined) use of GCs, immunosuppressive agents and biologics (*LoE 5, LoA 8.6*)

The recommended general sequential use of the three main categories of immunosuppressive agents in SjS is based on a similar approach to that reported for other SAD such as SLE or vasculitis, with no controlled studies supporting this approach in SjS. As a general rule, for most systemic involvements GCs (see recommendation 'GCs should be used at the minimum dose and length of time necessary to control active systemic disease *(LoE4, LoA9.6)*') may be considered the first-line option in patients with active systemic disease, and immunosuppressive agents and biologics as second/third line options to be used in patients intolerant or refractory to GCs, those with severe disease or those in whom long-term GC use is anticipated. In spite of the greater amount of scientific evidence data available for rituximab in comparison with GCs and immunosuppressive agents, the lack of licensing, the lack of controlled studies for systemic disease and the lack of head-to-head comparisons between rituximab and classic immunosuppressants (especially with respect to the safety profile) were issues to be considered. After an intense discussion among the TF members, the TF agreed to merge the two options as second-line therapies (adding a specific note about the use of rituximab as especially recommended for associated cryoglobulinemic vasculitis), always with a careful case-by-case assessment of the use of rituximab in an off-label context, evaluating potential benefits and adverse effects patient-by-patient (table 2), and taking into account the fact that their use will depend on drug availability and national regulations.

Unfortunately, after analysing the available evidence, no controlled data was identified to support a differentiated organ-guided therapeutic approach for systemic SjS, and some TF members recommend no strictly adherence to sequential therapy management, with an individualised therapeutic approach being preferable. However, on the basis of the results, principally from retrospective studies (online supplementary table S2), together with the clinical experience of the TF members, a list of consensus-based algorithms defining SOC and second/third line therapies was proposed for each clinical ESSDAI domain (figure 3A–I); Ro-associated congenital heart block (not included in the ESSDAI) was also included due to its prognostic significance. There was no consensus on the proposal to make recommendations for organ-specific maintenance therapeutic regimens.

Treatment of B-cell lymphoma should be individualised according to the specific histological subtype and disease stage (*LoE 4, LoA 9.7*)

Among the systemic manifestations of SjS, lymphoma is one of the worst complications, with standardised incidence ratios for B-cell lymphoma ranging between 7 and 9 in population-based studies and between 16 and 48 in hospital-based studies.[88] Although the vast majority of cells infiltrating the salivary glands of patients with primary SjS are T cells, the majority of lymphomas reported are of B-cell origin with a ratio between B and T-cell lymphomas of 15:1; three subtypes of B-cell lymphoma account for more than 90% of reported cases in primary SjS: mucosa-associated lymphoid tissue (MALT) lymphoma, other marginal zone lymphomas (MZL) and Diffuse large B cell lymphoma.[88] Following the diagnosis of lymphoma, therapy should be individualised according to the specific histological subtype defined according to the WHO 2016 classification[89] and the corresponding current therapeutic guidelines, with a personalised therapeutic approach driven by the haematologist/oncologist. For primary SjS-2002 patients diagnosed with low grade haematological neoplasia, some clinicians recommend a watchful waiting approach when lymphoma only affects the exocrine glands,[90] especially in the absence of constitutional symptoms, systemic features or B-cell activation biomarkers.[3] The decision to treat low-grade lymphomas or not must be discussed in a multidisciplinary committee, taking into account the fact that they are linked to the disease activity and are the ultimate stage of autoimmune B-cell activation. Moreover, low grade B-cell lymphomas have a potential risk of progression to more aggressive types of lymphoma.[3] In patients with disseminated MALT lymphoma or with concomitant high disease activity, chemotherapy may be considered on a case-by-case basis.[3] For patients with marginal zone lymphomas, small lymphocytic lymphoma (SLL) and lymphoplasmacytic lymphoma (LPL) in early disease stages (in particular, stage I or non-bulky stage II), treatment may include radiotherapy (with or without chemotherapy), although a watch-and-wait strategy could be an alternative to spare the side effects of therapy.[91] For patients with moderate/high grade haematological neoplasia, treatment is based on standard rituximab-based chemotherapy regimens. The benefit of adding rituximab to chemotherapy has been demonstrated in a meta-analysis in patients with follicular lymphomas, mantle cell lymphomas and other indolent lymphomas.[91] Rituximab plus fludarabine or bendamustine (BR) are the recommended first-line therapy for MZL, SLL and LPL; a recent study in 13 patients with pSjS-2002 (77% stage IV) complicated by MZL has reported the efficacy of the BR combination in all 13 cases, with improvement in the other SjS non-lymphomatous manifestations and with a good safety profile.[92]

DISCUSSION

The EULAR recommendations for the management of SjS with topical and systemic therapies management have been developed by a large, multidisciplinary, multiprofessional team. In summary, nine RCTs (only three including 120–130 patients), 18 prospective (all including between 10 and 50 patients) and five case-control studies were selected to support the scientific evidence presented here. This is a small number of studies that is not comparable with rheumatoid arthritis (RA) or with other, more closely-related diseases, such as SLE or systemic vasculitis. Therefore, the evidence accumulated in this century reveals SjS as a true orphan disease from a therapeutic point of view,[59 93] with the absence of any efficacious agent, a situation that is in clear contrast with the significant advances achieved in both basic and clinical research during this period. As a consequence of the limited evidence available, therapeutic decisions in daily practice are often based on a mix of reported expert opinions and personal experience, which may vary widely between countries: therefore, the present recommendations are based on the input of experts from 16 European countries and wide international representation from the other continents. In addition, SjS presents with a wide range of signs and symptoms (not only the key features of dryness, fatigue and pain, but also those derived from organ-specific systemic involvements and lymphoma), with

Ann Rheum Dis: first published as 10.1136/annrheumdis-2019-216114 on 31 October 2019. Downloaded from http://ard.bmj.com/ on February 3, 2023 by guest. Protected by copyright.

a large number of different specialties involved and, therefore, with a wide variety of potential interventions. Methodologically, we have also taken into account the continuous changes in classification criteria since 1986 and, in consequence, the continuous changes in the target population classified as primary SjS. For this reason, we decided, in the Population, Intervention, Comparison, Outcomes and Study design strategy, to focus on the evidence collected from therapeutic studies including pSjS-2002 patients, since these criteria have been used for a longer and more-recent period and because of their similarity with the recent 2016 American College of Rheumatology (ACR)/EULAR criteria.[16]

In SjS, we are very far from the 'disease modification' concept as the mainstay of treatment (as used in other diseases such as RA, a concept that allows the use of the term disease modifying antirheumatic drugs for many drugs that have demonstrated the ability to prevent structural damage progression in RA). A rapid overview of the LoE that support each statement (table 1) shows that all recommendations for managing oral and ocular dryness are principally supported by evidence extrapolated from Cochrane SLRs that evaluated their management in mixed aetiological populations; on the management/prevention of dryness-related complications (oral ulcers, candidiasis, caries/dental complications, ocular infections), the management of dryness other than oral or ocular, or the role of non-therapeutic interventions in dryness, there was a very limited number of studies carried out in 2002 primary SjS patients, and we recommend following published guidelines.[9–11 37 94] With respect to the most frequently used synthetic drugs (GCs and immunosuppressive agents), the available evidence came from isolated uncontrolled studies. The only exceptions were for hydroxychloroquine and rituximab, which were both tested in well-designed RCTs, although there were no statistically-significant differences with respect to placebo for the primary outcome (efficacy in dryness, fatigue and pain). With respect to systemic disease, the use of rituximab was supported by a large number of studies, mainly uncontrolled. We are also very far from defining specific treatment targets (especially searching for remission in non-systemic features), but it may be useful to use the EULAR disease activity states,[70] considering that any higher disease activity has to be regarded as inadequate disease control, thus mandating a therapeutic intervention, or that low disease activity achieved after therapy may be potentially acceptable for some organs. In any case, as stated in previous EULAR recommendations,[95] communication with the patient to clarify and agree on the treatment goal and the means to attain it is of utmost importance. Monitoring should be frequent in patients with systemic active disease, although the frequencies of follow-up examinations should be adjusted in accordance with the individual disease activity state,[70] namely, more frequently, such as monthly, when patients have high disease activity, and less frequently, such as every 6–12 months, when patients have low disease activity.

Lessons should be learnt from the first biological tested in primary SjS (infliximab). The excellent results of tumour necrosis factor-targeted therapies in RA led to their testing in patients with primary SjS, in spite of the large pathological and clinical differences between the two diseases. After the report of promising results in small open-label studies (one of which has been recently retracted by the authors), the first well-designed RCT showed no differences between the infliximab and placebo arms for the primary outcome. The same disappointing results have been obtained for other drugs reported as efficacious according to uncontrolled data (hydroxychloroquine and rituximab) without significant results for the primary outcomes when tested in RCTs. In SjS trials, two common issues may help to explain the negative results. The first is the choice of primary end-points. Most studies used composite primary outcomes based mainly on the subjective evaluation of dryness, fatigue, pain[96] ; the strong influence of personal and environmental factors on the intensity of this triad of symptoms could explain the lack of significant differences (a higher rate of placebo-related response), together with inadequate patient selection (too low degree of disease activity), the influence of concomitant drugs and the heterogeneity of diagnostic tests. The composite ESSDAI to measure systemic activity was used in the most recent RCT as a secondary end-point and frequently calculated retrospectively (although one of the weaknesses of this outcome could be the difficulty in differentiating activity due to chronic damage in different domains). The preliminary results of two new RCTs where ESSDAI was the primary end-point demonstrated efficacy of the active drug versus placebo (anti-CD40 and the combination of leflunomide and hydroxychloroquine).[97 98] The second issue is the limited number of patients randomised (no more than 50–60 patients per arm), taking into account the clinical and immunological heterogeneity of SjS as an SAD (such as SLE or systemic vasculitis); in SLE, the pivotal trials that allowed the licensing of belimumab were obtained from two trials including nearly 1000 patients each. Some promising results recently reported in small open-label studies testing biologics (belimumab, anakinra) must be confirmed in further large well-designed RCTs, while advance results of a large trial in primary SjS do not indicate a clinical benefit of abatacept.[99] The current therapeutic pipeline in SjS, as shown by the *clinicaltrials.gov* webpage, is that the biologic therapeutic approach overwhelmingly used in SjS until now (targeting B-cell depletion) is shifting towards the evaluation of biologics targeting cytokines, T-cells and intracellular signalling pathways.[100] With respect to ongoing trials, considerable interest is centred on the B cell survival factor (BAFF) pathway, investigating the effect of monoclonal antibodies targeting BAFF-receptor or the association between B-cell depletion and BAFF inhibition. In addition, studies are testing inhibition of other pathways activating B cells. Lastly, four ongoing trials are testing other pathways or the use of other cytokine-based therapies including tocilizumab, abatacept, filgotinib (a janus kinase inhibitor) and human recombinant Il-2.

Therapeutic research in SjS should probably be reconsidered in order to explore new pathogenic targets outside the glandular tissue (ie, neuroendocrine pathways), and to search for a more personalised therapeutic approach based on genetic, clinical, immunological and/or histopathological characteristics. It is not improbable that future RCTs would benefit from more selected patient cohorts, possibly including newly diagnosed SjS patients, the findings of early salivary gland ultrasound changes,[101–103] or evidence of early high disease activity at diagnosis[22] before permanent damage has been established and the changes are still reversible. Patients with sicca-limited disease differ from those with systemic disease, as do immune-negative patients from those carrying Ro autoantibodies or cryoglobulins, while recent etiopathogenic studies are beginning to divide SjS patients according to the genetic profile between those with or without a predominant IFN-I gene expression signature.[104–106] Sensitivity analyses searching for a differentiated response to therapies in these subsets of patients (sicca-limited vs systemic; Ro+ vs Ro-; positive vs negative salivary gland biopsy; positive vs negative IFN-I signature) might help to better delineate the therapeutic effect of a drug tested in primary SjS, although this would require a greater number of patients randomised than those included in reported trials.

Box 1 Research agenda

- Is there a specific, differentiated treatment of lymphomas related to SjS?
- Is combination therapy a potential intervention to explore in SjS?
- Exploring targeted therapies against Th17 cytokines, IFNα, RORγt expression, Janus kinases (JAKS), STATs and mTOR intracellular pathways or interleukin-1.
- Searching for predictive factors of biological response.
- Potential use of sequential or intralesional use of biological therapies.
- Encouraging the development of new and innovative therapies.
- In what proportion of systemic patients is induction therapy with current therapeutic options effective in inducing sustained remission?
- Is the use of immunosuppressive and biologic agents safe and efficacious in the absence of concomitant glucocorticoid treatment?
- How safe and efficacious is the off-label use of other biologics after rituximab has failed?
- Can we find predictors of differential response to the synthetic and biological drugs used in SjS?
- Can we predict who will maintain remission after withdrawal of glucocorticoids?
- Will we be able to develop precision (personalised, stratified) medicine approaches in SjS? (IFN signature +/-; immunological or histopathological markers +/-)?
- Which biomarkers will help identify better predictors of poor outcomes?

In conclusion, the 2019 EULAR recommendations are based on the recent evidence collected on the management of primary SjS patients and on discussions by a large, broadly-based international TF. The recommendations synthesise current thinking on SjS treatment in a set of overarching principles and recommendations. These have been informed by a specific SLR on the efficacy and safety of topical and systemic interventions, although the high-quality scientific evidence focused on primary SjS patients fulfilling the currently-accepted sets of criteria was limited. However, the TF is convinced that adhering to these recommendations, including shared decision-making, assessing disease activity regularly with the ESSDAI instrument, and applying the sequence of drugs as proposed, will improve overall outcomes in a clear majority of patients with SjS. New research information on treatment strategies, predictive markers and other aspects will soon become available and will probably require an update of the recommendations in coming years (see Future Agenda box 1). Until then, we hope that the current recommendations will be broadly applied in clinical practice and/or serve as a template for national societies to develop local recommendations.

Acknowledgements The Task Force gratefully acknowledges the financial support from EULAR and the support of the EULAR Standing Committee on Clinical Affairs (Prof. Ulf Müller-Ladner). The Task Force also expresses its sincere appreciation and gratitude to Désirée van der Heijde for her methodological suggestions and to the EULAR Secretariat and especially to Patrizia Jud, executive assistant, for the outstanding organisation. The authors also wish to thank David Buss (BA, Medical Writer) for technical assistance. Simon Bowman's salary is part funded by the Birmingham Biomedical Research Centre. These recommendations are also endorsed by the European Reference Network (ERN) for rare and low prevalence complex diseases ReCONNET (Rare Connective and Musculoskeletal Diseases Network).

Contributors PB-Z and SR performed the systematic literature review (SLR); MR-C and PB-Z drafted the manuscript. BK supervised the methodology of the SLR and the Delphi process. All authors edited the manuscript and accepted its final form.

Funding This study was funded by European League Against Rheumatism.

Competing interests MR-C reported consultancy for BMS, Gilead; FB reported consultancy GSK, UCB, ONO, Roche; MB consultancy and/or unrestricted grants from Medimmune, Amgen, GSK, Janssen, AbbVie; SB Participation in Abbvie Advisory Board; RP for Abbvie, Novartis, Ab2 Bio ltd, Celltrion healthcare; RC: speaker's and/or consultation fee from: Abbvie, BMS, Celgene, Gilead, Janssen Cilag, Lilly, MSD, Novartis, Pfizer, Roche and Sanofi; MR reported consultancy for Abbvie, BMS, Celgene, Janssen Cilag, Novartis, Pfizer, Roche and Sanofi; W-FN reported consultancy for GSK, Novartis, BMS, MedImmune and Abbvie; AGT reported Research Grants From Pfizer, Novartis, Abbvie, Genesis, GSK, Janssen, Eli-Lilly, Through The Research Accounts Of The University Of Athens; CHS: Consultant for Novartis in 2018; PW consultant for Roche, Novartis, Pfizer, Abbvie, Lilly, Gedeon-Richter, Sandoz, Medac, MSD, Sanofi-Aventis. TM reported consultancy Novartis; BAF reported consultancy for Novartis, Roche, MedImmune, BMS.

Bowman[9]; on behalf of the British Society for Rheumatology Standards, Guideline and Audit Working Group

Key words: Sjögren's, guideline, management, sicca

GUIDELINES

Background

Primary Sjogren's Syndrome (pSS) is a classic, immune-mediated, condition of unknown aetiology characterized by focal lymphocytic infiltration of exocrine glands [1]. Patients characteristically complain of drying of the eyes and mucosal surfaces along with fatigue and arthralgia. There is an association with autoimmune thyroid disease, coeliac disease and primary biliary cirrhosis. Systemic features include inflammatory arthritis, scLE, immune thrombocytopenia (ITP), vasculitis with purpura, salivary gland inflammation, neuropathies, interstitial lung disease (ILD) and a 5–10% lifetime risk of B cell lymphoma [2, 3].

This guideline reviews the treatment of the glandular and systemic features of pSS The management of the glandular features includes conserving, replacing and stimulating secretions. Systemic features may require system-specific therapy and immunomodulatory treatment. Holistic

NICE has accredited the process used by the BSR to produce its guidance for the management of primary Sjögren's Syndrome in adults. Accreditation is valid for 5 years from 10 June 2013. More information on accreditation can be viewed at www.nice.org.uk/accreditation. For full details on our accreditation visit: www.nice.org.uk/accreditation.

management is important and many patients benefit from non-pharmacological therapies and general support.

Diagnosis

Patients commonly present with dryness of the eyes [4] and mouth [5]. In the early stages they may complain of grittiness rather than dryness of the eyes, and the mouth symptoms may require prompting. Fatigue and arthralgia are almost universal. There is often a considerable delay between symptom onset and diagnosis. The most widely accepted current classification criteria for pSS and those referred to in this guideline are the American-European Consensus Group (AECG) criteria [6]. The 2016 ACR–EULAR criteria have just been published [7] derived from criteria proposed by the Sjögren's International Collaborative Clinical Alliance (SICCA) [8]. The populations described by both criteria are very similar.

For a definite diagnosis the AECG criteria require four out of six of dry eye symptoms, dry mouth symptoms, objective ocular dryness (Schirmer's test $\leqslant$5 mm in 5 min or van Bijsterveld score $\geqslant$4), objective oral dryness (unstimulated salivary flow rate $\leqslant$0.1 ml/min or positive salivary scintigraphy and sialography), positive anti-Ro/La antibodies, labial gland focus score $\geqslant$1 including at least one of the last two objective features.

The 2016 ACR–EULAR classification criteria are based on the weighted sum of five items and require a total score $\geqslant$4 to meet the criteria for diagnosis where the presence of anti-Ro antibodies or focal lymphocytic sialadenitis with a focus score of $\geqslant$1 score 3 each and where abnormal ocular staining score $\geqslant$5, Schirmer's test result of $\leqslant$5 mm/5 min and unstimulated salivary flow rate of $<$0.1 ml/min score 1 each.

Investigations

The best-described autoantibodies in pSS are the anti-Ro and anti-La antibodies, which are routinely identified as part of the ENA laboratory screen. About two-thirds of patients with primary SS have anti-Ro antibodies and/or anti-La antibodies. These figures, however, depend on the classification criteria used, referral bias and access to labial gland biopsy.

Need for guideline

pSS typically presents in women in their fifth or sixth decade, although up to 10% of cases occur in men and it is also seen in younger people. Studies using the AECG criteria have estimated the prevalence in women in the UK at 0.1–0.4% [9]. Patients present to primary care physicians, general physicians, ophthalmologists and dental practitioners many of whom lack specialist knowledge regarding the treatment of this patient cohort.

Objective of guideline

This document aims to provide a pragmatic, practical guideline for the management of adults with pSS.

Target audience

The target audience includes rheumatologists, general physicians, general practitioners, specialist nurses and other specialists (e.g. ophthalmologists, dental practitioners and ENT specialists) who will review patients with pSS during their clinical practice. The guideline should also be of relevance to specialist registrars in training and specialist nurses.

Areas not covered

The management of children with SS is not specifically covered by this guideline although the general management of children and teenagers with SS is similar to that for adults with special emphasis on the importance of good dental care and hygiene to preserve dental health.

SS is very rare in teenagers and there are only anecdotal reports worldwide of its occurrence in pre-pubertal children so we would recommend that children and teenagers presenting with symptoms suggestive of SS are referred to a specialist centre for evaluation and treatment.

In addition this guideline does not cover the detailed management of patients with secondary Sjögren's. Where patients have secondary SS their systemic management should address the primary disease but the advice on topical management contained in these guidelines is applicable to sicca symptoms from any cause. This guideline does not cover the detailed management of patients with lymphoma, who should be managed in conjunction with oncologists and haematologists.

Stakeholder involvement

The multidisciplinary team involved in producing these guidelines was led by Dr Elizabeth Price, Consultant Rheumatologist, who chaired the team, undertook the systematic review and led the development of the guideline. The management of eye disease was led by Miss Saaeha Rauz, Clinical Senior Lecturer and Clinical Ophthalmologist, who also acted as The Royal College of Ophthalmologists' representative. Dr Anwar Tappuni, Reader and Academic Lead for Oral Medicine, was the main contributor to the oral section and Dr Nurhan Sutcliffe, Consultant Rheumatologist, acted as the lead for the systemic section. Ms Katie L. Hackett was the British Health Professionals in Rheumatology's representative and lead for non-pharmacological management. Dr Francesca Barone, Clinician Scientist and Honorary Consultant Rheumatologist, was the lead for the Delphi process and supervised Dr Guido Granata, Visiting Fellow, who undertook the Delphi analysis. Professor Wan-Fai Ng, Consultant Rheumatologist, Dr Benjamin A. Fisher, Senior Clinical Lecturer and Honorary Consultant Rheumatologist, Dr Michele Bombardieri, National Institute for Health Research Senior Clinical Lecturer in Rheumatology, Dr Elisa Astorri, Clinical Research Fellow, Miss Genevieve Larkin, Consultant Ophthalmologist, and Professor Simon Bowman, Consultant and Honorary Professor of Rheumatology, provided further review and clinical input. Mrs Bridget Crampton contributed as a patient representative and Dr Benjamin Empson provided GP representation.

Conflict of interest statement

Any conflicts of interest among members of the working party were fully declared. The declared conflicts of interest are included at the end of the article.

Rigor of development and limitations

A search was undertaken for all relevant evidence in the Cochrane Library, MEDLINE (Ovid and PubMed) and EMBASE from 1990 to current (February 2015 and updated September 2015). Additional references were added through regular updates to the draft recommendations up to January 2016. Non-English language papers were excluded unless a translation was published. We also excluded treatments not currently available in the UK unless there was a significant likelihood they would become available in the near future. Identified papers were reviewed, categorized and the level of evidence graded according to international criteria from Ia through to IV and A through to B [10]. See supplementary data Search history and supplementary table S1, available at *Rheumatology* online, for full details of search criteria and level of evidence definitions.

The guideline was developed in line with the BSR Guideline Protocol using Appraisal of Guidelines for Research and Evaluation II methodology (http://www.agreetrust.org/). The wording and content of the recommendations were subjected to a formal Delphi process [11] using online surveys to determine the eventual strength of agreement (SOA) for each recommendation. The Delphi method was developed in the 1950s. It describes a process whereby a group of experts anonymously reply to questionnaires and subsequently receive feedback in the form of a statistical representation of the group response, after which the process repeats itself. The goal is to reduce the range of responses and arrive at something closer to expert consensus. In our case each recommendation was rated on a score from 1 (no agreement) to 10 (complete agreement). The results were collated and circulated to the group prior to the second round. We then included recommendations with a mean SOA score of $\geqslant 7$ plus $\geqslant 75\%$ respondents scoring $\geqslant 7$. This is expressed as the mean score with percentage $\geqslant 7$ in parentheses, for example, SOA 7 (75%) with a maximum of 10 (100%).

The guideline

Eligibility criteria

This guideline is primarily aimed at the management of patients with pSS as defined by the AECG [6] or ACR–EULAR (in press) criteria but the advice on topical management contained in these guidelines is applicable to sicca symptoms from any cause.

Exclusion criteria

Sicca symptoms can result from a variety of causes, some of which may be reversible if addressed. Drugs are a common cause of sicca and many different drug groups have been implicated. Potential causative agents include those with anti-cholinergic activity such as anti-depressants, anxiolytics and anti-psychotics; muscarinic anatagonists such as tamsulosin hydrochloride and ipratropium hydrochloride; anti-histamines; opiates; anti-hypertensives including beta-blockers and angiotensin converting enzyme (ACE) inhibitors; and proton pump inhibitors such as omeprazole. Avoiding these entirely may not be practicable, but use should be minimized in the presence of sicca symptoms if possible.

Sicca symptoms are commonly seen following head and neck radiotherapy and may respond to topical treatment and pilocarpine (see below). Dehydration and acute anxiety may cause temporary sicca symptoms. Rarely, primary salivary gland pathology other than SS including sarcoidosis, IgG4 disease [12] and graft *vs* host disease [13] may be implicated. Salivary gland aplasia and ductal atresia [14] are both rare causes of oral sicca and viral infections including hepatitis C and HIV can cause salivary gland disease with hypertrophy and sicca symptoms.

Xerostomia can be a feature of oral dysaesthesias with no objective reduction in salivary flow rate. Oral dysaesthesia or burning mouth syndrome is a chronic pain condition currently classified as a neuropathic disorder. Such patients may complain of a constellation of oral symptoms, including burning sensations, unusual taste as well as oral dryness, and their symptomatology is not uncommonly associated with anxiety states and clinical depression. There may also be a history of low back pain, FM and irritable bowel syndrome [15].

A syndrome comprising histological evidence of sialadenitis, nodular osteoarthritis and xerostomia has been described [16], but in view of the frequency of the individual clinical features and the demographics of the individuals with these conditions, clustering of these entities could also be expected to occur on a simple statistical basis.

Ageing *per se* is not a cause of xerostomia. Although there is a broadly linear reduction in the amount of functional acinar tissue within the salivary glands over time, this does not lead to clinically significant salivary gland hypofunction in normal subjects [17]. Xerostomia in the ageing population is more a function of intercurrent disease and medication rather than loss of secretory ability [18].

The guideline

The guideline covers management of the eye and mouth manifestations, systemic dryness and systemic disease in general with comments on the management of pregnancy and lymphoma in patients with SS. For each section we have reviewed and summarized the available evidence and then listed the recommendations that achieved a mean SOA score of $\geqslant 7$ plus 75% of respondents scoring $\geqslant 7$ after the second round of the Delphi process as described above. In general we would recommend initial symptomatic treatment of sicca manifestations combined, if appropriate, with systemic management.

Treatment of sicca manifestations

All patients with pSS (and sicca from other causes) should be offered symptomatic treatment of dryness. The sicca

Table 1 Dry eye management summary

Level 1: mild dry eye	Level 2: moderate dry eye	Level 3/4: severe dry eye (ophthalmology only)
Features	Features	Features
Tear film break-up time: >9 s	Tear film break-up time: 5–9 s	Tear film break-up time: <5 s
Staining: VB score = 0–3, OSS = 0	Staining: VB score = 4–5, OSS = 1–6	Staining: VB score = 7–12, OSS = 5–12
Management	As for mild plus:	As for moderate plus:
Educational and environmental	Moisture chamber spectacles	Lubricants
Lubricants	Lubricants	High concentration hyaluronates 0.2–0.4%
Hypromellose	Carmellose 1% eye	Hyaluronates with Xanthan gum
Carbomer gels	Low concentration hydroxypropylguar eye drops	Soybean with phospholipids
Carmellose 0.5%	Sodium hyaluronate eye drops 0.1–0.18%	Mucolytics for filaments, e.g. acetylcysteine
Ointments	For corneal inflammation consider prednisolone 0.5% non-preserved 2–3× daily (ophthalmology only)	Higher strength topical steroids for short term use, e.g. dexamethasone 0.1%
Lid hygiene	For blepharitis consider metallomatrix proteinase inhibitors, e.g. doxycycline 50 mg od (ophthalmology only)	Ciclosporin-containing drops or ointment
Liposomal sprays available over the counter to replace tear film oil layer	Punctal plugging—punctal or intracanalicular plugs (ophthalmology only)	Nutritional tear substitutes
	Secretagogues	Autologous or allogeneic serum eye drops (available via specialist commissioned centres only)
	Oral pilocarpine max 5 mg 4× per day (start with 2.5 mg od and build up)	Permanent punctal occlusion via cautery of all four puncta
	Pilocarpine 4% (3 drops = 5 mg) for those who are unable to swallow (palliative care pathway [56])	Periorbital botulinum toxin for significant blepharospasm
		Bandage contact lenses
		Amniotic membrane overlay or corneal grafting for significant corneal ulceration and corneal melt or perforation

Based upon the DEWS workshop and the Meibomian Gland Dysfunction Workshop [19]. VB: van Bijsterveld Schema; OSS: ocular surface staining score.

symptoms classically affect eyes and mouth but many patients also experience a chronic, dry cough due to drying of the mucosal surfaces and, in women, vaginal dryness. In general treatment of sicca symptoms should aim to conserve, replace and stimulate secretions while reducing inflammation.

Management of ocular manifestations of SS

Dry eyes may be classified as mild, moderate or severe based on the presence of both symptoms and signs [19]. Definitions are included in Table 1 and rely on knowing the tear film break-up time and/or the ocular surface staining score. In the past, staging of eye disease has not routinely been carried out by optomoterists and ophthalmologists but this is changing with routine staging being introduced for other eye diseases. In practice rheumatologists and GPs will either rely on patient reported symptoms or simple Schirmer's testing to assess severity of disease but, by definition the majority of patients with SS will have severe dry eye (Schirmer's $\leqslant$5 mm in 5 min and tear break-up time $\leqslant$5 s).

It should be remembered that in Sjögren's associated dry eye all three layers of the tear film are affected. There is mucosal layer deficiency, aqueous deficiency and meibomian gland deficiency, all of which need to be addressed.

Ocular—conservation of tears and meibomian gland secretions

Systemic medications that exacerbate dryness should be avoided if possible. These include those with anti-cholinergic activity (psychotropics including antidepressants, anxiolytics and anti-psychotics), muscarinic antagonists (e.g. tamsolusin hydrochloride; ipratropium hydrochloride), anti-histamines, opiates, anti-hypertensives (e.g. beta blockers; ACE inhibitors) and proton pump inhibitors (e.g. omeprazole), although the latter may have an important role in the treatment of laryngotracheal reflux.

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

Studies have shown that humidification of cabin air increases tear-film stability [20] in normal individuals and by extrapolation it is advised for dry eye. Patients consistently report feeling more comfortable in a humidified environment.

Two randomized placebo controlled trials showed improvements in symptoms of dry eye following oral supplementation with omega 3 fatty acids, with improvement in both Schirmer's test and markers of ocular inflammation [21, 22]. There is some low quality evidence that omega 7 derived from sea buckthorn oil provides some symptomatic relief of dry eye symptoms from both a small, open label, informal study [23] and a double-masked, randomized, parallel trial [24]. The evidence was felt to be of insufficient strength to include this as a recommendation within the final guideline.

Adequate meibomian gland secretion is essential to prevent evaporative tear loss. There is evidence that it is useful to enhance meibomian gland secretion using either warm compresses or commercially available microwavable lid warming compresses [25]. Patients should be advised to perform lid hygiene if required using proprietary wipes (available over the counter) or with a weak solution of bicarbonate. Useful guides for patients are available on both the National Health Service and the National Institute for Health and Care Excellence (NICE) websites [26, 27].

A recent report by the American Academy of Ophthalmologists reviewed the evidence for the oral antibiotics doxycycline, minocycline and azithromycin in the management of ocular surface disease arising from disorders of the meibomian glands. They identified eight studies that documented an improvement in meibomian gland-related ocular surface disease after treatment with these agents, although side effects were common. Only one study was a randomized, controlled trial. They concluded oral antibiotics may be an effective treatment for ocular surface disease that results from meibomian gland disease [28]. Two small observational, open label clinical studies of topical azithromycin ophthalmic solution 1% (twice daily for 2 days and once daily on days 3–28) in subjects with symptomatic meibomian gland disease, but not specifically SS, showed improvement in both clinical signs and symptoms of disease [29, 30]. Expert advice in the UK is to consider doxycycline 50 mg od for a minimum of 3 months in patients with persistent meibomian gland inflammation and blepharitis not responding to topical management. If treating young patients it is important to remember that doxycycline is contraindicated in those $<$12 years of age. Minocycline is avoided because of the small risk of causing drug-induced lupus.

Wearing spectacles reduces surface evaporation of tears by up to 30% and the effect can be optimized by the use of moisture chamber spectacles [31, 32]. The latter can be manufactured by opticians or purchased on-line. There is evidence supporting the early use of punctal plugs [33, 34], which improve symptoms of dry eye significantly more than artificial tears alone.

First line treatment should be with visible plugs. If this successfully improves symptoms or signs, and there is no evidence of excess watering or over flow of tears, then permanent punctal occlusion can be achieved with punctal cautery. Intracanalicular plugs are effective but increase the risk of granuloma and infection [35, 36] and are not visible on examination. Referral to an ophthalmologist is advised and it is important to remember that plugs are available in different sizes and the puncta should ideally be measured with a calliper prior to selection and insertion of an appropriately sized plug. Improperly sized plugs may fall out, with accompanying deterioration in symptoms; alternatively loose plugs will allow tear flow, or cause irritation.

Recommendations for conservation of tears and meibomian gland secretions

(i) Treatment should begin with conservation of tears by humidification and avoidance of systemic medication that exacerbates dryness. Level of evidence Ib/A; SOA 8.9 (97%).
(ii) Patients should be advised to stimulate meibomian gland secretion daily using either warm compresses or commercially available microwavable lid warming compresses or other devices and perform lid hygiene if required using proprietary wipes (available over the counter) or with a weak solution of bicarbonate. Level of evidence III/C; SOA 8.9 (93.3%).
(iii) In patients with persistent meibomian gland inflammation and blepharitis, treatment with doxycycline 50 mg od for a minimum of 3 months may be effective. Level of evidence IV/D; SOA 8.83 (92.9%).
(iv) Early referral to an ophthalmologist for review and consideration of insertion of punctal plugs or cauterization of puncta is recommended. Level of evidence II/B; SOA 9.27 (100%).

Ocular—replacement of tears and meibomian gland secretions

Liposomal sprays (available over the counter but not currently FP10 prescribable) reduce evaporative tear loss and replace the meibomian gland layer and have been shown to significantly reduce sicca symptoms [37].

To replace the aqueous tear film start with simple lubricating drops using the most cost-effective options. In general start with low viscosity simple drops such as hypromellose and escalate as symptoms dictate. Given the severity of dry eye disease in primary SS, it is unlikely, however, that simple drops will be sufficient to control the disease. When prescribing take into account the bottle or device used to apply the drops. In particular consider ease of application and expiry dates. See advice below and in accompanying Table 2 for preparations.

Multi-use ophthalmic preparations rapidly become colonized with bacteria and are associated with high rates of pathogenic organisms on conjunctival culture [38]. As a result, the majority of multi-dose preparations contain a preservative to limit bacterial, fungal and amoebic ocular infections and prolong shelf life by preventing biodegradation. High concentrations of certain preservatives

			HydraMed [sodium hyaluronate (0.2% w/v), polysaccharide (0.2% w/v)]

A selection of ocular lubricants available in preserved and non-preserved forms. Most are available both over the counter and on prescription, some are prescription only and others are over the counter only. [a]Contains benzalkonium chloride (should be avoided). [b]Over the counter only. [c]Prescription only. MD: multidose bottle; SDU: single dose units.

may damage and irritate ocular tissue and this effect is enhanced in those with ocular surface disease. Benzalkonium chloride is the most frequently used preservative in topical ophthalmic preparations and its epithelial toxic effects are well established [39]. Preserved preparations should be avoided in patients using eye drops long term (for >3 months), instilling drops >4 times daily or those with ocular surface disease (effectively the majority

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

of patients with pSS). Some eye drops are available as single-use preservative-free preparations. Although convenient these are often costly and require good manual dexterity to use. Increasingly eye drops are available in multi-use bottles with preservative systems that biodegrade on contact either with light or with the ocular surface. Other preservative-free multidose systems use a pump or vacuum system preventing regurgitation into the bottle and obviating the need for preservatives altogether.

Autologous or allogeneic serum eye drops are the only available nutritional tear substitutes and are effective and well tolerated by patients [40, 41]. However, they are very expensive to produce and are only available from commissioned specialist centres.

Recommendations for replacement of tears and meibomian gland

(i) Recommend liposomal sprays to reduce evaporative tear loss and replace the meibomian gland layer. Level of evidence III/C; SOA 8.29 (92.8%).
(ii) Start with simple lubricating drops using the most cost-effective options (see Table 2 for preparations). Level of evidence IV/D; SOA 9.3 (93.3%).
(iii) Avoid preservative-containing preparations. Level of evidence I/A; SOA 9.21 (92.9%).
(iv) Patients with severe dry eye, not responding to conventional treatment may be referred to specialist centres for consideration of autologous or allogeneic serum eye drops. Level of evidence IIb/B; SOA 9.5 (100%).

Ocular—anti-inflammatory

There is evidence supporting the use of topical anti-inflammatories under ophthalmic supervision in patients with persistent corneal inflammation. Low dose steroid-containing eye drops are recommended for short term use and have been shown to be both safe and effective [42]. Longer term use of topical steroids has been associated with an increased risk of glaucoma and cataract and should be avoided [43]. In general the use of topical steroids should be limited to patients under supervision by an ophthalmologist. For longer term use ciclosporin-containing eye drops have been shown to reduce subjective symptoms and improve objective signs of inflammation in patients with both primary and secondary SS [44–46]. Ciclosporin 0.1% (Ikervis®) is licensed and NICE approved as a possible treatment for people with dry eye disease that has not improved despite treatment with artificial tears (NICE TAG 369 December 2015 [47]) but must initially be prescribed by a sub-specialty ophthalmologist. An unlicensed veterinary ointment (Optimmune®, ciclosporin 0.2%) or a preservative-free eye drop available via Moorfields Pharmaceuticals may be used as alternatives. All forms of topical ciclosporin may be used off licence for patients <16 years of age.

Topical NSAIDs such as diclofenac and indomethacin have been shown to improve ocular discomfort but reduce corneal sensitivity and may predispose to further corneal damage and should therefore be used only with caution in patients with SS [48, 49].

Recommendation for anti-inflammatory treatment of dry eye

(i) Low dose steroid-containing eye drops are recommended for short term use under ophthalmic supervision only. Level of evidence Ib/A; SOA 9.64 (100%).
(ii) Longer term use of topical steroids should be avoided. Level of evidence Ib/A; SOA 9.64 (100%).
(iii) Ciclosporin-containing eye drops or ointments may be used under ophthalmic supervision in patients with evidence of chronic inflammation. Level of evidence Ib/A; SOA 9.38 (100%).
(iv) Topical NSAIDs such as diclofenac and indomethacin should be used with caution under ophthalmic supervision only. Level of evidence IIb/B; SOA 9.86 (100%).

Ocular—stimulate

Oral pilocarpine treatment can improve ocular dryness and tear film break-up time and increase goblet cell density thus improving the mucous layer [50–54]. Symptomatic and objective improvements are seen in more than a third of patients, although side effects (headache, increased sweating) may limit its use in some.

The recommended starting dose is 5 mg once daily, escalating at weekly intervals as tolerated to 5 mg qds (with meals and at bedtime) but if response is insufficient, the dose can be increased to 30 mg daily, if tolerated well; discontinue if no improvement after 2–3 months. Contraindications include uncontrolled asthma and chronic obstructive pulmonary disease, uncontrolled cardiorenal disease and acute iritis. Common side effects include dyspepsia, diarrhoea, abdominal pain, flushing and increased urinary frequency. There is evidence from an observational study that it is both safe and effective in children and young people as young as 9 years of age [55]. In patients intolerant of pilocarpine tablets, using topical ocular drops orally allows delivery of a smaller dose of drug and may be better tolerated. The Palliative Care Formulary suggests 2–3 drops of pilocarpine 4% eye drops is equivalent to 4–6 mg oral pilocarpine; however this is an off-licence use [56].

Recommendations for stimulation of ocular secretions

(i) A trial of pilocarpine 5 mg once daily increasing stepwise to 5 mg qds is recommended for patients with significant sicca symptoms and no contraindications to its use. Level of evidence IIb/B; SOA 9.08 (92.3%).

Miscellaneous treatments for dry eye and ocular complications

Mucolytic eye drops, for example, acetylcysteine 5–10% non-preserved, are useful for patients with mucous threads or ocular surface filaments [57] and have also

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

been shown to improve tear break-up time and Schirmer's tests in patients with meibomian gland disease [58].

Some patients with severe dry eye develop an associated blepharospasm. There are small case series describing a good response to botulinum toxin injections in these circumstances [59, 60].

For severe dry eye bandage scleral contact lenses, designed to protect the surface and create an optimized environment for healing, may be indicated. These lenses vault over the corneal surface and rest on the sclera. They are rigid and gas-permeable and require specialist fitting and manufacture. They are only available in specialist centres for severe corneal disease refractory to other treatment measures. A number of studies have shown significant decreases in corneal staining with scleral contact lens wear with significant improvements in dry eye symptoms and quality of life [61–63].

Corneal grafting or amniotic membrane overlay may occasionally be indicated for cases of significant corneal ulceration and corneal melt [64]. Neuropathic pain (when dry eye symptoms outweigh clinical findings) is a recognized entity. Neuropathic pain strategies should be considered for these patients [65].

Recommendations for severe, complicated dry eyes

(i) Mucolytic eye drops should be prescribed for patients with mucous threads or ocular surface filaments. Level of evidence III/C; SOA 9.38 (100%).
(ii) Patients with severe dry eye and associated blepharospasm may benefit from referral to a specialist centre for consideration of botulinum toxin treatment. Level of evidence III/C; SOA 9.17 (100%).
(iii) Patients with severe dry eye and corneal ulceration, not responding to conventional treatment, may be referred to specialist centres for consideration of bandage contact lenses or amniotic membrane grafting or corneal grafting for perforations. Level of evidence III/C; SOA 9.15 (92.9%).

Management of oral manifestations of SS

Dry mouth (xerostomia) is a hallmark of pSS and the majority of patients suffer from both reduced salivary flow rate and increased viscosity of saliva due to relative deficiency of the aqueous component, which may compromise oral health.

Complications of long-term xerostomia include oral discomfort and soreness and a burning sensation in the mouth. An increased rate of dental caries, excessive tooth wear and premature tooth loss are often observed. Patients struggle to achieve a high standard of oral hygiene and may suffer from halitosis. Patients tolerate dentures poorly and often complain of difficulty retaining them in the mouth with sore, ulcerated gums as a consequence of rubbing. Many patients suffer recurrent infections including parotitis, intraoral candidiasis and angular cheilitis. Dysarthria, dysphagia and dysgeusia (distorted sense of taste) are seen in established disease.

The evidence surrounding periodontal disease in Sjögren's is conflicting, with some studies suggesting an increased prevalence of periodontal disease [66] but others not [67].

Effective management of the dry mouth is important for the maintenance of oral health and to improve oral health-related quality of life as well as general health and quality of life.

Oral—conserve

Many patients with pSS anecdotally report improvement in symptoms following humidification of room air and patients frequently report worsening of symptoms in dry and air-conditioned environments.

Patients with pSS have higher rates of the cariogenic bacterium *Streptococcus mutans*, dental caries and dental loss compared with controls despite apparently good dental care [68, 69]. Dental caries is considered to be a diet-mediated disease, as sugars are essential in the caries process. This has been confirmed in several large-population-based studies that have shown a significant association between total sugar intake and the development of dental decay over time in a normal population. Twice daily use of fluoride toothpaste reduced but did not eliminate the association between diet and dental decay in these studies [70–72].

Given their enhanced risk of dental decay patients with pSS should be advised to practice excellent oral hygiene and avoid sweetened food and drink on a regular basis. Assessment by an Oral Medicine specialist and/or regular visits to a general dental practitioner are recommended to monitor and treat the oral manifestations of SS with the emphasis on preventative dental care.

The optimum concentration of fluoride in standard toothpaste has been calculated assuming a normal salivary flow rate and taking into consideration the availability of fluoride in normal saliva. Concentrations of fluoride in standard over-the-counter toothpastes vary from 500 to 1000 parts per million (ppm) and occasionally higher. Prescription toothpastes contain fluoride concentrations of between 2800 and 5000 ppm. Dry mouth patients will need a higher concentration of fluoride in toothpaste to compensate for the lack of salivary fluoride. A number of studies [73–75] and a Cochrane review [76] have concluded that caries protection is increased with higher fluoride concentrations. A systematic review of the literature and a Delphi consensus exercise by a national panel of experts in North America concluded that there was good evidence that a prescription strength, home-use, fluoride gel or paste should be used in all patients with pSS [77].

Acidic products and those containing sugar should not be prescribed for dentate patients since maintaining a neutral oral pH environment may reduce the development of dental caries [78].

There is evidence that in addition to the total sugar content of the diet, frequency of sugar intake is implicated in dental decay [77]. In light of this we recommend that patients with pSS avoid food and drinks other than plain

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

water between meals and from 1 h before bedtime and all through the night.

Patients should be advised to brush their teeth at least twice daily (but not immediately after eating) including before bed at night using a pea sized amount of high fluoride toothpaste and use fluoride-containing tooth mousse or gel on teeth twice daily. They should avoid alcohol-containing mouth washes, sugary or fizzy drinks and frequent snacking [77].

Chlorhexidine is an effective antiseptic that inhibits plaque formation on teeth and is useful for controlling gingivitis [79]. Many oral specialists and dentists recommend an alcohol-free chlorhexidine mouth wash in pSS patients as preventative treatment for gum disease. It can be used twice daily for a maximum of 2 weeks every 3 months but over use can lead to staining of teeth.

Recommendations for conservation of moisture and oral hygiene

(i) Patients should be advised to humidify the environment. Level of evidence IIV/D; SOA 9.13 (100%).
(ii) Patients should be advised to practice excellent oral hygiene, limit sugar intake and avoid food and drinks other than plain water between meals and from 1 h before bedtime and all through the night. Level of evidence IV/D; SOA 9.8 (100%).
(iii) Assessment by an oral medicine specialist and/or regular visits to a general dental practitioner typically at 3–6 monthly intervals are recommended to monitor and treat the oral manifestations of SS. Level of evidence IV/D; SOA 9.8 (100%).
(iv) Aim to avoid acidic products and those containing sugar when prescribing for dentate patients. Level of evidence IV/D SOA 9.87 (100%).
(v) Patients should be advised to brush teeth at least twice daily (but not immediately after eating) including before bed at night using a pea sized amount of high fluoride toothpaste and use fluoride-containing oral mousse or gel on teeth twice daily. Level of evidence I/A; SOA 9.8 (100%).
(vi) Alcohol-free chlorhexidine mouth wash used twice daily for a maximum of 2 weeks every 3 months can help prevent gum disease but over use can lead to staining of teeth. Level of evidence IV/D; SOA 9.0 (100%).

Oral—replace

It is common practice to manage mild symptoms by recommending that patients sip water, suck ice or chew sugar-free gum [77, 80]. More severe dryness can be managed with commercially available topical and systemic treatments for dry mouth.

Saliva substitutes provide symptomatic momentary relief of oral dryness. A Cochrane review of the effectiveness of topical treatments for dry mouth from any cause, including parallel and crossover randomized controlled trials of lozenges, sprays, mouth rinses, gels, oils, chewing gum and toothpastes did not find strong evidence for their effectiveness [81, 82], but in the experience of the working group patients report increased oral comfort from their use.

The ideal preparation will have neutral pH and contain fluoride and other electrolytes, mimicking the composition of natural saliva. Saliva substitutes are available commercially in the form of oral sprays, gels and rinses. Most are freely available over the counter and some are prescription only. The choice will depend upon patient preference and local availability. Fluoride-containing, neutral pH preparations should be prescribed for dentate patients (see Supplementary table S2, available at *Rheumatology* online, for products available in the UK). Preparations with acidic pH and/or without added fluoride should only be used in edentulous patients.

There is limited evidence that an oxygenated glycerol triester saliva substitute spray is more effective than a water-based electrolyte spray in older patients with dry mouth [83].

Patients with Sjögren's are at increased risk of frictional oral ulcers [84]. There is evidence that polyvinylpyrrolidone and sodium hyaluronate oral gel (Gelclair) may be helpful in patients with recurrent oral ulceration post-chemotherapy but no published studies of its effectiveness in SS [85]. A list of commercially available oral preparations is provided for reference in Supplementary table S2, available at *Rheumatology* online.

Recommendations for replacement of oral secretions

(i) Patients should be advised to use a neutral-pH fluoride-containing mouth wash, gel or spray as required for symptomatic relief. Level of evidence III/C; SOA 9.43 (92.8%).

Oral—stimulate

Topical saliva stimulants

Although no study directly links improved salivary flow to caries prevention, expert opinion acknowledges that increasing saliva flow is likely to reduce caries incidence in the longer term.

Chewing sugar-free gum increases saliva production and there is some evidence that in addition to its value as a non-sugar sweetener xylitol may have a role in caries prevention in its own right [86, 87]. A recent Cochrane review of the evidence for xylitol concluded that over 2.5–3 years of use, a fluoride toothpaste containing 10% xylitol may reduce caries by 13% when compared with a fluoride-only toothpaste, but that there was insufficient evidence to determine whether any other xylitol-containing products could prevent caries in infants, older children or adults [88].

Many patients chew or suck sugar-free sweets and report benefit, but there is no published evidence supporting this. Certain foodstuffs may be more effective at stimulating saliva than others, but acidic products and those containing sugar should be avoided because of their cariogenic potential. A small cross-over study in normal volunteers assessed the efficacy of yogurt and lemon juice as salivary stimulants and found that both were

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

effective but yogurt more so than lemon juice compared with baseline, leading them to suggest that yogurt is a potential candidate for the treatment of dry mouth and warrants further study [89].

Some commercially available salivary stimulants are available in the UK. There is little convincing evidence of efficacy and conflicting results from the few reported studies [90, 91].

A small single-blinded, open-label, cross-over clinical study of a branded dry mouth product (Xerostom) containing olive oil, betaine and xylitol in a population with polypharmacy-induced xerostomia resulted in increased unstimulated whole salivary flow rates, reduced complaints of xerostomia and improved xerostomia-associated quality of life. No clinically significant adverse events were observed [92]. The preparation is non-acidic and contains both fluoride and calcium so may be suitable for patients with SS, although there are no published studies in this patient population.

Anhydrous crystalline maltose is available over the counter or on-line and has been shown to increase salivary flow rates with minimal adverse effects in small, observational studies [93] but is not available on prescription.

There is some experimental evidence for both acupuncture and mild electrical stimulation improving salivary flow rates. Published studies are generally small, usually observational and are not specifically looking at patients with SS [81]. There were adverse effects reported with the use of acupuncture, but these were mild and of short duration. There were no reported adverse effects from electrostimulation, with some evidence for improved salivary flow. Further larger studies are planned but neither is currently routinely available in the UK for the treatment of sicca [94]. A gel-releasing device (reservoir) worn in the mouth has been trialled and may be effective in some patients [95], but more research is needed.

Recommendations for mechanical stimulation of oral secretions

(i) Patients should be advised to chew xylitol-containing sugar-free gum. Level of evidence III/C; SOA 9.67 (100%).

Systemic stimulants

Pilocarpine hydrochloride (Salagen) is licensed for use in the UK for dry mouth and eyes in SS. It acts as an agonist on muscarinic-cholinergic receptors to stimulate secretion. It is effective in both primary and secondary SS. There are a number of randomized, controlled trials in patients with Sjögren's confirming significant symptomatic improvement and objective evidence of increased salivary flow in patients treated with pilocarpine [96–98]. Evidence suggests that at least half of patients respond although it can take up to 12 weeks to see a therapeutic benefit. In long term use levels of candida colonization reduce [99]. Side effects are common and dose dependent. They include sweating, palpitations and flushing. See 'Ocular—stimulate' section for more detail on the use of pilocarpine and adverse effects.

Cevimeline is another muscarinic agonist that stimulates fluid secretion generally [100, 101] but has higher affinity for muscarinic receptors located on lacrimal and salivary gland epithelium and may be associated with fewer side effects compared with pilocarpine [102]. However, this drug is not currently licensed for use in the UK.

There is some limited evidence that the H2 blocker nizatadine mildly improves (20% over baseline) objective and subjective measure of oral dryness and is well tolerated although it is not licensed for this indication in the UK [103].

Recommendations for systemic stimulation of secretions

(i) A trial of pilocarpine 5 mg once daily increasing stepwise to 5 mg qds is recommended for patients with significant sicca symptoms and no contraindications to its use. Level of evidence IIb/B; SOA 9.77 (100%).

Treatment of oral candida

Oral candida is a frequent problem in patients with Sjögren's-associated dry mouth [104] and patients have high levels of candida carriage despite good dental hygiene [105]. Patients may have visible white plaques (simple infection) or erythematous infection, when they present with a red, raw tongue or oral cavity. Clinical experience suggests that whereas topical agents such as nystatin may be adequate to treat simple infection, oral fluconazole is required to treat erythematous infection. The presence of dentures creates an environment where candida may become persistent.

Angular cheilits, where patients present with dry, fissured erythematous lesions in the corner of their mouths, is another manifestation of candidal infection in SS. It can be effectively treated with miconazole topically for 2 weeks, using a clean cotton bud to apply to each side to prevent cross-contamination and persistence of infection [106].

Recommendations for treatment of oral candida

(i) In simple candida infection (visible white plaques) treat with oral nystatin liquid 1 ml five times daily for 7 days. Consider repeating the treatment for 1 week every 8 weeks if frequent recurrence. If the patient has erythematous infection manifesting as a red, raw tongue or oral cavity and commonly seen in denture wearers, use fluconazole 50 mg od for 10 days. Level of evidence IV/D; SOA 9.86 (100%).

(ii) Treat angular cheilitis with miconazole topically for 2 weeks, using a clean cotton bud to apply to each side to prevent cross-contamination and persistence of infection. Level of evidence IV/D; SOA 9.86 (100%).

Management of salivary gland enlargement

Some patients with pSS have recurrent or persistent salivary gland enlargement. This may occur during disease

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

activity flares or may reflect duct obstruction due to strictures, stones or inspissated secretions.

Parotid sialography is a very specific diagnostic test for pSS [107] that involves injection of contrast materials into the salivary ducts and is associated with a small risk of infection, ductal perforation and allergic reactions. Intraductal injection of contrast can assess the ductal system and exclude strictures [108]. Interventional sialoendoscopy has been reported to be useful in patients with SS with chronic obstructive sialadenitis unresponsive to medical therapy. Under local anaesthesia the orifice of the salivary gland is intubated and the scope advanced, with continuous saline lavage. This allows obstructing plaques to be washed out and any strictures dilated. Symptomatic improvement was achieved in 85% of patients using this technique [109]. However, sialoendoscopy is not widely available and no large scale or long term studies have been published.

In contrast salivary gland US is non-invasive, well tolerated by patients and easily repeatable. US allows assessment of the architecture of the major salivary glands and, used in conjunction with Doppler signals, it may help differentiate between benign and malignant lesions. In some centres salivary gland US is utilized as a diagnostic screening tool and studies confirm it has a high positive predictive value of 85% with good correlation between abnormalities on US and salivary gland histology [110]. Baseline ultrasound is recommended in patients with salivary gland swelling to look for active inflammation, infection and stones. Consider repeating the US if there is a history of new persistent or recurrent salivary gland swelling to monitor for disease progression and development of complications [111].

If there is acute inflammation in the absence of infection and stones then a short course of oral prednisolone or an intra-muscular injection of depomedrone (typically 120 mg) will often settle the glandular swelling promptly (anecdotal evidence). There is anecdotal evidence that massaging the glands can help reduce discomfort in chronically inflamed glands.

Recommendations for management of salivary gland enlargement

(i) Consider salivary gland US to look for active inflammation, infection and stones. Level of evidence IV/D; SOA 9.7 (100%).
(ii) If acute inflammation in the absence of infection and stones then a short course of oral prednisolone or an intra-muscular injection of depomedrone will often settle the glandular swelling. Level of evidence IV/D; SOA 9.01 (100%).
(iii) Massaging the glands can help reduce discomfort in chronically inflamed glands. Level of evidence IV/D; SOA 9.31 (92.8%).

Systemic dryness

Many patients report a chronic dry cough due to drying of mucosal surfaces. Humidification of inspired air is reported to help by some patients [112]. Pilocarpine improves secretions in general and anecdotally reduces the frequency and severity of dry cough. A mucolytic agent (i.e. carbocysteine) reduced the viscosity of sputum, improved the ability to cough up bronchial secretions, and reduced cough frequency and shortness of breath in a double blind controlled study of patients with chronic bronchitis [113]. There is anecdotal evidence it helps in patients with SS and an associated chronic, dry cough. Concomitant use of oral acetylcysteine with AZA and steroids should be avoided given evidence of increased hospitalization and death in a group of patients with pulmonary fibrosis (but not Sjögren's) treated with triple therapy *vs* placebo [114]. It should be remembered that chronic dry persistent cough may be a sign of ILD and should prompt appropriate investigations.

Females with SS frequently complain of vaginal dryness [115]. Pilocarpine may help this by non-specifically stimulating secretions. There is evidence supporting the use of non-hormonal moisturisers in the treatment of vaginal dryness from any cause [116–118]. Vaginal moisturizers applied on a regular basis have an efficacy equivalent to local hormone replacement for the treatment of local urogenital symptoms such as vaginal itching, irritation and dyspareunia [116]. Patients with SS have both vaginal dryness and atrophy of the genital skin [119]. There is evidence supporting the use of topical oestrogen-containing products in patients with post-menopausal vaginal atrophy and dryness [116]. Creams and pessaries are equally effective and although systemic absorption can occur with local preparations, there is no current evidence of an increased risk of endometrial thickening [116]. The use of local hormone replacement therapy can reduce the frequency of recurrent urinary tract infections in post-menopausal women [116].

Recommendations for management of systemic dryness

(i) A trial of pilocarpine 5 mg once daily increasing stepwise to 5 mg qds is recommended for all patients with significant systemic dryness and no contraindications to its use. Level of evidence IV/D; SOA 9.08 (92.3%).
(ii) Patients with vaginal dryness should be advised to use a non-hormonal vaginal moisturiser with or without a topical oestrogen-containing product. Level of evidence I/A; SOA 9.8 (100%).

Treatment of systemic disease

Systemic (extra-glandular) features are seen in ~70% of patients with SS and are severe in about 15% [120]. The most commonly involved organs are joints, lungs, skin and peripheral nerves [3]. Raynaud's and thyroid disease tend to be commoner in females and lung involvement and peripheral neuropathies are commoner in those with a disease duration of > 10 years [2]. Other systemic features may include autoimmune liver disease, renal involvement, scLE, ITP, myositis, monoclonal gammopathy of uncertain significance and lymphoma. There are also common overlapping conditions, most notably thyroid disease in up to

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

20% [121], primary biliary cirrhosis in 8% [122] and coeliac disease in 4.5% [123].

Although significant systemic complications are more common in the Ro/La positive group [3] recent evidence suggests that systemic complications also affect a reasonable proportion of the antibody negative group with SS [124] suggesting that all patients with SS warrant consideration of active treatment.

Non-pharmacological interventions for systemic disease

A recent systematic review evaluated the evidence for non-pharmacological interventions for pSS and found that much of the evidence was inconclusive [125]. The available studies suggest that patients with SS benefit from moderate to high intensity exercise with improvements in aerobic capacity, fatigue scores, physical functioning and depression [126].

Lifestyle management strategies may benefit SS patients if fatigue is significantly affecting their ability to perform daily activities. Strategies recommended by NICE guidance for fatigue include sleep management, activity management, relaxation techniques, cognitive behavioural therapy and graded exercise therapy. See relevant NICE guidance on management of fatigue in adults.

Many patients report benefit from joining a Sjögren's support group. The British Sjögren's Syndrome Association provides information and advice for members via their website, a quarterly magazine and a dedicated telephone helpline (www.bssa.uk.net). Arthritis Research UK (www.arthritisresearchuk.org) provides helpful information and leaflets on SS, anti-rheumatic drugs and lifestyle advice.

Recommendations for non-pharmacological interventions for systemic disease

(i) Regular exercise and, where appropriate, a graded exercise programme are recommended for patients with SS presenting with fatigue. Level of evidence IIb/B; SOA 9.33 (93.3%).
(ii) Provide written patient information and details of appropriate support groups and on-line resources. Level of evidence IV/D; SOA 9.8 (100%).

Immunomodulation for systemic disease

Early and aggressive immunomodulation is recommended for RA and increasingly for other autoimmune diseases but not well established for SS. An evidence base is lacking and patients with SS often tolerate these drugs poorly. There is, however, increasing insight into the pathogenesis of SS and interest in its therapeutic management with an increase in the use of conventional disease modifying drugs and research interest in the development of targeted biological agents. The guideline working group considered the evidence supporting the use of corticosteroids, disease modifying drugs, biologics and other drugs alongside their own experience. Where disease modifying drugs are used they should be monitored in accordance with the recommendations of the latest BSR DMARD guidelines (in press). Biologics are not currently NICE approved or funded for the treatment of SS.

Systemic pulmonary manifestations of Sjogren's include ILD and cysts. Usual interstitial pneumonitis and non-specific interstitial pneumonitis are the most commonly reported. In general systemic steroids are recommended as first line treatment, then subsequently various immunosuppressives, including CYC and AZA, rituximab and anti-malarials depending on steroid responsiveness [127–129]. A broad range of neurological complications have been described in Sjögren's. A diffuse sensorimotor neuropathy, confirmed on nerve conduction testing, may affect $>15\%$ of patients with Sjögren's [130]. There are anecdotal reports of benefit from rituximab, immunoglobulins, AZA and HCQ [130].

Trigeminal neuropathy/neuralgia has been described in up to 5% of patients with Sjögren's. It does not usually respond to treatment with steroids and in general is treated as for trigeminal neuralgia of unknown cause. Mononeuritis multiplex is probably seen in $<3\%$ of Sjögren's patients over their lifetime. It is associated with vascultis and may respond to treatment with steroids and CYC [131]. Autonomic neuropathy is common and correlates with patient reported outcomes [132]. It may respond to simple, symptomatic treatment. SS myelopathy can mimic multiple sclerosis. Patients may present with paraplegia, sensory changes and bladder dysfunction. Steroids and CYC may be helpful [133].

Signal hyperintensities on brain MRI have been described in patients with Sjögren's and have been postulated to indicate the presence of an underlying cerebral vasculopathy [134]. Correlation with serological abnormalities and clinical symptoms is poor, however. Neuromyelitis optica spectrum disorder is associated with the presence of aquaporin-4 antibodies and although seen in association with Sjögren's may not be a direct neurological complication of Sjögren's. This patient group benefits from aggressive and ongoing immunosuppression [135].

Although significant renal impairment is rare, tubulointerstitial nephritis and, more rarely, immune complex glomerulonephritis are well described renal manifestations of Sjögren's. In those patients with tubulointerstitial nephritis there is a mononuclear lymphocytic infiltrate on renal biopsy, and treatment with mycophenolate and steroids improves the renal function [136].

Corticosteroids

Prednisolone has been shown to help systemic features including lung disease [127–129] cytopaenias [137], and, in combination with CYC or chlorambucil, neurological involvement [138, 139]. Small studies of low dose prednisolone (5–7.5 mg per day) have shown improvements in sicca symptoms and modest improvements in salivary flow [140].

There are no controlled trials of pulsed i.v. methylprednisolone or i.m. depomedrone in Sjögren's, although there are anecdotal reports of successful use of pulsed steroids in patients with Sjögren's associated lung disease [141], ganglionopathy [142], myelopathy [133] and renal involvement [143].

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

Recommendations for corticosteroids

(i) Corticosteroids are not recommended for the routine treatment of pSS although intermittent short courses of oral or intramuscular steroid are effective for systemic flares of disease and steroids may be used for significant organ manifestations with or without additional immunosuppressive treatment. Level of evidence III/C; SOA 9.2 (100%).

(ii) Low dose oral prednisolone is effective in treating persistent constitutional symptoms in patients who have failed to respond to HCQ or other immunosuppresants. Level of evidence IIb/B; SOA 8.92 (100%).

Recommended DMARDs

HCQ

Evidence of efficacy of HCQ in SS is variable. A number of studies [144–147] suggest modest improvements in ocular and oral dryness, lowering of ESR and immunoglobulin levels, together with reductions in fatigue levels and joint pain in patients treated with HCQ.

The JOQUER study, a randomized controlled trial of HCQ 400 mg daily, which studied a group with mild disease (i.e. no systemic disease), failed to reach its primary outcome of a 30% improvement in two out of three outcomes (visual analogue scale (VAS) of pain, dryness, fatigue) at 6 months, but it did confirm a decrease in immunoglobulin levels and ESR in treated patients. The study was extended to 48 weeks with all patients being prescribed HCQ between weeks 24 and 48. Although there was a suggestion of clinical and serological improvement in the cohort taking a full 12 months of HCQ, in the open-label extension this did not reach statistical significance [148].

A meta-analysis of six earlier trials involving 140 female patients failed to identify a clear benefit of antimalarials but commented that the available evidence was of poor quality and called for more and better quality research [149].

All members of the guideline working group recommended a therapeutic trial of HCQ treatment in patients with evidence of systemic disease starting at 400 mg once daily decreasing after 6 weeks to 200 mg once daily with monitoring as per BSR guidelines.

Recommendations for HCQ

(i) HCQ up to a maximum dose of 6 mg/kg is recommended for patients with pSS especially those with skin and joint disease and fatigue. Patients should be monitored for evidence of a clinical and/or biological response (e.g. falling immunoglobulin levels). If no response after 12 months of treatment consider stopping. Level of evidence IIa/B; SOA 9.64 (100%).

AZA

AZA has been reported as helpful in case reports for systemic complications such as lung disease [150], myelopathy [151] and cytopaenias [152], but a double blind placebo controlled trial in a small cohort of patients with uncomplicated disease suggested that it did not have a routine role in treatment and was associated with a high frequency of side effects [153]. There is, however, some evidence for efficacy of AZA in both usual interstitial pneumonitis and non-specific interstitial pneumonitis, the most commonly reported forms of ILD in Sjögren's [128, 129, 154, 155]. Discontinuation rates of AZA due to non-respiratory side effects may be higher than for mycophenolate although efficacy is similar in patients with ILD [156].

Recommendations for AZA

(i) AZA is not routinely recommended for management of uncomplicated Sjögren's but may be considered in patients with systemic complications, for example, lung disease, myelopathy and cytopaenias. Level of evidence III/C; SOA 9.09 (100%).

MTX

MTX is the drug of choice for patients with significant inflammatory arthritis [157]. There are case reports of successful treatment of Sjögren's associated inclusion body myositis [158] and myelopathy [159] with MTX. An open label, pilot study of weekly MTX in 17 patients showed improvement in sicca symptoms, parotid swelling, dry cough and purpura but no improvement in objective parameters of dry eyes and mouth [160].

Recommendations for MTX

(i) MTX may be useful for those patients with an associated inflammatory arthritis but there is not enough evidence for its routine use as a disease-modifying drug for those with sicca symptoms alone. Level of evidence IV/D SOA 9.54 (100%).

Mycophenolate

A single centre, open-label pilot trial of mycophenolate in 11 patients reported subjective improvement of ocular dryness and reduction in artificial tear use, but objective evidence of significant glandular improvement in only two patients with short disease duration. There was significant reduction in hypergammaglobulinaemia and RF levels and increase in complements and white cell levels [161]. A case report [162] documents successful treatment of refractory agranulocytosis with mycophenolate in a patient with primary Sjögren's. There is emerging evidence supporting the use of mycophenolate in patients with CTD related ILD including SS [163, 164]. Mycophenolate has been show to stabilize scleroderma associated ILD in a randomized controlled trial [165]. There are to date no similarly robust clinical trials supporting mycophenolate in Sjögren's associated ILD, but there are anecodatal reports and small case series suggesting benefit [166, 167].

Recommendations for mycophenolate

(i) The use of mycophenolate may be considered in patients with systemic complications such as cytopaenias or lung disease. Level of evidence III/C; SOA 9.1 (100%).

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

Ciclosporin A

There are anecdotal reports of successful treatment of Sjögren's associated interstitial cystitis [168], annular erythema [169, 170], red cell aplasia [171] and pneumonitis [172] with oral ciclosporin. An open-label phase II study of low dose ciclosporin A (2 mg/kg) showed reductions in joint swelling and tenderness, a fall in the EULAR SS Disease Activity Index and Hospital Anxiety Questionnaire and improvements in both the physical and mental health domains of the Short Form 36 [173].

Recommendations for ciclosporin A

(i) Ciclosporin A is not routinely recommended for management of uncomplicated Sjögren's, although it may be helpful in patients with significant joint involvement. Level of evidence III/C; SOA 8.58 (85.7%).

CYC

There are no controlled trials of CYC in SS and in general its potential toxicity would preclude routine use. However, there are published case reports and series documenting successful treatment of Sjögren's associated myelopathy [133, 138] with pulsed monthly CYC, refractory thrombocytopaenia [174] with pulsed followed by oral CYC, glomerulonephritis [143, 175] with both pulsed and oral CYC and lung disease [176] with pulsed intravenous CYC.

Recommendations for CYC

(i) The use of CYC (usually in combination with steroids) may be considered in patients with organ threatening systemic complications such as CNS, renal or lung disease. Level of evidence III/C; SOA 9.09 (100%).

DMARDs not routinely recommended

LEF

Two phase II open label pilot studies found very modest benefits and multiple side effects [177, 178].

Recommendations for LEF

(i) LEF is not routinely recommended for pSS. Level of evidence III/C; SOA 9.8 (100%).

Penicillamine

A prospective open label study found very modest benefits and multiple side effects [179].

Recommendations for penicillamine

(i) Penicillamine is not routinely recommended for pSS Level of evidence III/C; SOA 10 (100%).

Biologics for systemic disease

Rituximab

There is accumulating evidence from published case studies and case series supporting the use of rituximab in patients with active, systemic pSS.

Rituximab has evidence of efficacy from small case series and case reports in the treatment of Sjögren's related lymphoma, ITP, cryoglobulinaemia and neurological disease [180–190].

A number of open label studies and randomized controlled trials have looked at the effect of rituximab on the fatigue and sicca manifestations (see Supplementary table S3, available at *Rheumatology* online, for a summary). An open label study of 12 patients [191] observed modest improvements in patient reported fatigue and oral dryness at 26 weeks following a single treatment course of rituximab. The TEARS (Tolerance and Efficacy of Rituximab in primary Sjogren's syndrome) study [192] found no significant differences between treatment and placebo arms in the primary end point (an improvement of at least 30 mm in 2 of 4 VAS scores at week 24 following a single treatment course of rituximab). However, there was a significant improvement in the fatigue VAS scores in the treatment group at 6 and 16 weeks. The multicentre UK based TRACTISS (TRial of Anti-B Cell Therapy In patients with primary Sjogren's Syndrome) trial [193] has recently been completed. Although preliminary analysis has shown no consistent benefit on fatigue, dryness and salivary flow, further analysis of data is being conducted. A recent study has suggested that patients with higher levels of B cell infiltration within the parotid glands are more likely to respond to rituximab, suggesting that we may in future be able to target therapy more effectively [194]. There is evidence that B cell activating factor is upregulated after rituximab treatment [195] and this may explain the observation in the TEARS study that patients had improved at 4 months but deteriorated again by 6 months [192].

The dose, duration between doses and treatment response in the smaller studies and case series are listed in Supplementary table S3, available at *Rheumatology* online, but in the TEARS study [192] patients received just two 1 g pulses of rituximab 2 weeks apart at baseline, whereas in the TRACTISS study [193] this was repeated at 6 months.

In conclusion there is currently insufficient evidence to recommend routine use of rituximab in those with predominantly fatigue and sicca manifestations but good evidence for its use in systemic complications and lymphoma. Use of Rituximab in pSS is not currently NICE approved and is not routinely funded for the treatment of SS with the exception of those patients presenting with lymphoma.

Recommendations for rituximab

(i) Rituximab is recommended for specialist use in patients with significant systemic manifestations refractory to treatment with steroids and other immunosuppressives. It has a role in those with lymphoma, ITP, vasculitic neuropathy and cryoglobulinaemias. Level of evidence IIb/B; SOA 9.43 (100%).

Biologics where more evidence of efficacy is required

Belimumab

Belimumab is a human mAb that inhibits B cell activating factor. An open-label study of belimumab, in 30 patients

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

with pSS demonstrated a significant improvement in the EULAR SS Disease Activity Index Score from baseline with particular improvement in non-malignant glandular swelling [196]. Although not currently routinely used in Sjögren's syndrome, belimumab has also been reported to be of benefit in case reports in combination with rituximab [197] and further trials of belimumab, including a combined study with rituximab, are currently underway.

Recommendations for belimumab

(i) Belimumab is not currently recommended although it merits further study. Level of evidence IIb/B; SOA 9.46 (92.8%).

Abatacept

Abatacept was well tolerated in one open label pilot study and fatigue and health related quality of life improved significantly over a 24-week treatment period [198]. There is a phase II study currently underway (https://clinicaltrials.gov/ct2/show/NCT02067910).

Recommendations for abatacept

(i) Abatacept is not currently recommended although it merits further study. Level of evidence III/C; SOA 9.46 (92.8%).

Biologics not currently recommended

Anti-TNF therapy

Initial open label studies of anti-TNF agents suggested some benefit [199–201] but subsequent randomized double-blind controlled trials have failed to show clinical or serological improvement in patients with Sjögren's following treatment with anti-TNF in the form of etanercept [201] or infliximab [203].

Recommendations for anti-TNF therapy

(i) Anti-TNF therapies are not recommended for treatment of pSS. Level of evidence Ib/A; SOA 9.38 (85.7%).

IFNα

IFNα therapy via the oro-mucosal route is not currently available in the UK for the treatment of SS, although there is some evidence of efficacy with moderate improvements in unstimulated salivary flow rates in phases II and III studies [204–207].

Recommendations for IFNα

(i) IFNα therapy via the oro-mucosal route is not currently recommended for the treatment of SS. Level of evidence Ib/B; SOA.

Anti-IL1 (anakinra)

A double-blind, placebo-controlled parallel group study [208] of anakinra in pSS failed to reach its primary end point, although more patients on the active drug than on placebo reported a 50% reduction in fatigue.

Recommendations for anti-IL1

(i) Anakinra (an anti-IL-1 receptor antagonist) is not recommended for the treatment of pSS. Level of evidence Ib/A; SOA 9.82 (100%).

Tociluzimab

Tocilizumab, an anti-IL-6 receptor antibody, is used routinely in the treatment of patients with RA but is not licensed for use in SS. A single case report describes successful treatment of refractory organizing pneumonia associated with Sjögren's [209], but there is insufficient evidence to recommend its use pending further studies.

Recommendations for tociluzimab

(i) Tociluzimab (an anti-IL-6 receptor antibody) is not recommended for the treatment of pSS. Level of evidence III/C; SOA 9.82 (100%).

Efalizumab

A small, open label study of three patients showed no clinical improvement and a significant increase in inflammation on minor salivary gland biopsy with the development of new anti-dsDNA antibodies in two of the three subjects [210].

Recommendations for efalizumab

(i) Efalizumab is not recommended for the treatment of pSS. Level of evidence III/C.

Other potential treatments for systemic disease

IVIG

There is evidence supporting the use of immunoglobulin therapy in Sjögren's associated sensorimotor and non-ataxic sensory neuropathy from retrospective and observational cohorts and case reports [211, 212]. Immunoglobulin treatment has also been used successfully in refractory Sjögren's associated myositis not responding to conventional treatment [213]. There is no evidence for its routine use in patients without significant complications.

Recommendations for IVIGs

(i) Immunoglobulin treatment is not routinely used in pSS, although it may be effective in Sjögren's associated myositis and neuropathies and its use in these conditions may be justified if the patient has failed to respond to treatment with steroids and conventional immunosuppression. Level of evidence III/C; SOA 9.43 (100%).

Colchicine

There are case reports describing successful treatment of Sjögren's associated hypergammaglobulinaemic purpura [214], granulomatous panniculitis [215] and pericarditis [216] with colchicine.

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

Recommendations for colchicine

(i) Colchicine may be considered as adjunctive treatment in patients with cutaneous manifestations or pericarditis not responding to HCQ or other treatments. Level of evidence III/C; SOA 8.45 (85.7%).

Dapsone

There are case reports describing successful treatment of Sjögren's associated scLE and urticarial vasculitis [217], pyoderma gangrenosum [218] and cutaneous vasculitis [219] with dapsone.

Recommendations for dapsone

(i) Dapsone may be considered as adjunctive treatment in patients with cutaneous manifestations not responding to HCQ. Level of evidence III/C; SOA 8.8 (100%).

Topical tacrolimus

There are case reports describing successful treatment of annular erythema associated with SS [220] with topical tacrolimus. Studies of tacrolimus suggest an increased incidence of skin cancer, so it should be used sparingly for a limited amount of time.

Recommendations for tacrolimus

(i) Topical tacrolimus may be considered as adjunctive treatment in patients with cutaneous manifestations not responding to HCQ. Level of evidence III/C; SOA 8.75 (100%).

Other drugs not recommended

Dehydroepiandrosterone substitution treatment

Two double-blinded, randomized studies of DHEA treatment in SS failed to show any symptomatic improvement or changes in clinical or serological measures in treated patients compared with placebo [221, 222].

Recommendations for DHEA

(i) DHEA substitution treatment is not recommended in pSS. Level of evidence Ib/A; SOA 9.45 (100%).

Management of pregnancy

Fertility is normal in patients with pSS, although there is an increased risk of recurrent miscarriage in the Ro/La$^+$ group [223–225]. Neonatal lupus rash occurs in about 5% of live births in Ro/La positive women usually appearing at 6 weeks of age and lasting about 17 weeks before fading and clearing completely. A few children have persistent depigmentation or telangiectasia [226]. Congenital heart block occurs in $<2\%$ of pregnancies in women with anti-Ro or anti-La antibodies and may be detected by US scanning from about 16 weeks' gestation [227]. There is evidence that in anti-Ro positive women, fetal atrioventricular (AV) time intervals are longer and heart rates slightly lower compared with controls. Fetuses with normal AV time intervals at 18–24 weeks had normal electrocardiographic results at birth. Hence serial Doppler echocardiographic measurement of AV time intervals is suggested as a useful method for surveillance of these high-risk pregnancies [228]. Following an affected pregnancy the risk of congenital heart block goes up to 17% for subsequent pregnancies. Seventy per cent of affected children survive, but nearly all require pacemakers in the first few months of life [229]. There is some evidence from longitudinal, observational studies that primary SS mothers deliver significantly earlier, give birth to babies with lower birth weight and have complications during deliveries more frequently than women in the general population [227]. Other, very rare, complications include hepatitis and cytopenias affecting the newborn. Only a handful of cases have been reported in the literature and in the majority of cases the child has improved spontaneously [230].

Successful pregnancies are, however, increasingly common in patients with Sjögren's. There is evidence that low-dose aspirin initiated in early pregnancy improves placental implantation and reduces the incidence of both pre-eclampsia and intra-uterine growth retardation [231, 232]. The working group therefore recommended that in Sjögren's pregnancy one should consider low dose aspirin to improve placental implantation and monitor closely with serial US. It is safe to continue HCQ throughout pregnancy with evidence in patients with SLE of improved outcomes for the mother and no detrimental effects on the child [233–236]. Refer to the BSR and BHPR guideline on prescribing drugs in pregnancy and breastfeeding [235, 236].

Recommendations for management of pregnancy

(i) Consider low dose aspirin to improve placental implantation. Level of evidence IIb/B; SOA 8.27 (92.8%).
(ii) Monitor closely with serial US if anti-Ro and/or anti-La positive and consider referral to specialist centre. Level of evidence IIb/B; SOA 9.71 (100%).
(iii) Review all medication in pregnancy. HCQ may be continued throughout pregnancy and breastfeeding. Level of evidence I/A; SOA 7.91 (85.7%).

Assessment of lymphoma risk

The risk of lymphoma development in patients with primary SS increases from 3% in the first 5 years to 9.8% at 15 years, that is, up to 40 times the population risk [237–239]. The presence of lymphadenopathy, parotid enlargement, palpable purpura, low serum C4 levels and cryoglobulins are the most consistent predictors of future risk [240] and may increase the risk of future development of lymphoma up to 5-fold [238]. The detection of germinal centre-like structures or a focus score $\geqslant 3$ on light microscopy in diagnostic salivary gland biopsies from patients with pSS may suggest a future higher risk for lymphoma development [241]. The majority of lymphomas are of the mucosa-associated lymphoid tissue type. The median age of onset is mid-50s and the diagnosis of Sjögren's generally predates the lymphoma by a mean of 7 years [237].

Downloaded from https://academic.oup.com/rheumatology/article/56/10/e24/3895127 by guest on 03 February 2023

Commonest sites of presentation include the parotid and other salivary glands, followed by the orbits, stomach, thyroid, lung, upper airways and rarely other sites [242]. Presentation is usually with a firm, palpable swelling within the gland. GI tract lymphoma may present with chronic diarrhoea, malabsorption and weight loss [243].

Recommendations for assessment of lymphoma risk

(i) Review high risk patients regularly and warn patients to report firm, painless glandular swelling that does not settle. Level of evidence IV/D; SOA 9.86 (100%).

Management of lymphoma

US allows assessment of any new swelling within the major salivary glands and, used in conjunction with Doppler signals, may help differentiate between benign and malignant lesions [111].

Biopsy is usually necessary to confirm the diagnosis. CT scanning is helpful for staging. Treatment can be variable and may include a watch and wait approach in patients with localized low-grade lymphoma or radiation alone but is generally with surgical excision followed by radiotherapy, chemotherapy, generally including rituximab, or a combination of the two. There are regularly updated UK guidelines available. The prognosis is generally good with a complete response to initial treatment in >90% and 5-year disease-free survival >75% [242], but splenomegaly, low serum C3, levels, neutropenia and lymphopenia may indicate a higher risk of poor outcome [240]. Refer to Haematology/Oncology for detailed advice on management.

Recommendations for management of lymphoma

(i) Investigate suspicious lesions with local US, biopsy and CT chest, abdomen and pelvis for staging. Level of evidence III/C; SOA9.77 (100%).

Conclusion

pSS is a chronic, debilitating condition that warrants effective management. All patients should be counselled and offered topical management for sicca symptoms. Systemic treatment should be considered early in those with constitutional symptoms.

Applicability and utility

Key standards of care and potential organizational barriers to implementation

pSS is associated with significant direct and indirect costs and represents a significant impact on the healthcare system [244, 245]. The initial management of SS includes educating the patient on appropriate management and initiating simple treatments such as moisturizing eye drops and fluorinated mouth gels. This is best done by a physician with an interest and some background knowledge. Patients also benefit from the additional time and expertise of an appropriately trained specialist nurse. A baseline ophthalmic and oral medicine specialist assessment are recommended. Appropriate early management will improve outcomes for patients and prevent the development of excess dental caries and potentially reduce the future health care needs of these patients. A multi-disciplinary clinic setting has been shown by one specialist unit to provide a cost effective and high quality environment for patient care while facilitating involvement in research [246].

Mechanism for audit of the guideline

An audit pro forma to assess compliance with these guidelines is available on the BSR website.

Funding: No specific funding was received from any bodies in the public, commercial or not-for-profit sectors to carry out the work described in this manuscript.

Disclosure statement: B.A.F. has received honoraria from Novartis and Medimmune. W.-F.N. has provided scientific consultancy for Takeda, MedImmune, UCB, Sanofi, Eli-Lily, AbbVie and have received research support from Resolve Therapeutics. S.B. has consulted for a number of Pharmaceutical Companies in the field of clinical trial design Sjogren's Syndrome (AstraZeneca/Medimmune, BMS, Celgene, Eli Lilly, Glenmark, GSK, MTPharma, Novartis, Ono, Pfizer, Takeda, UCB, xtlbio). F.B. works in a unit that has received funding from GSK and USB. All other authors have declared no conflicts of interest.

Merkel,[35] Stanislav Sierakowski,[23] Richard M. Silver,[36] Robert W. Simms,[35] John Varga,[37] and Janet E. Pope[38]

This criteria set has been approved by the American College of Rheumatology (ACR) Board of Directors and the European League Against Rheumatism (EULAR) Executive Committee. This signifies that the criteria set has been quantitatively validated using patient data, and it has undergone validation based on an external data set. All ACR/EULAR-approved criteria sets are expected to undergo intermittent updates.

SSc Criteria were developed collaboratively

Frank van den Hoogen, Dinesh Khanna, Jaap Fransen, Sindhu R. Johnson, Murray Baron, Alan Tyndall, Marco Matucci-Cerinic, Raymond Naden, Thomas A Medsger Jr., Patricia Carreira, Gabriela Riemekasten, Phillip Clements, Christopher P Denton, Oliver Distler, Yannick Allanore, Daniel E Furst, Armando Gabrielli, Maureen Mayes, Jacob M van Laar, James R Seibold, Laszlo Czirjak, Virginia Steen, Murat Inanc, Otylia Kowal-Bielecka, Ulf Müller-Ladner Gabriele Valentini, Douglas Veale, Madelon Vonk, Ulrich A Walker, Lorinda Chung, Dave Collier, Mary Ellen Csuka, Barry J Fessler, Serena Guiducci, Ariane Herrick, Vivian Hsu, Sergio Jimenez, Bashar Kahaleh, Peter Merkel, Stanislav Sierakowski, Richard Silver, Rob Simms, John Varga, Janet E Pope

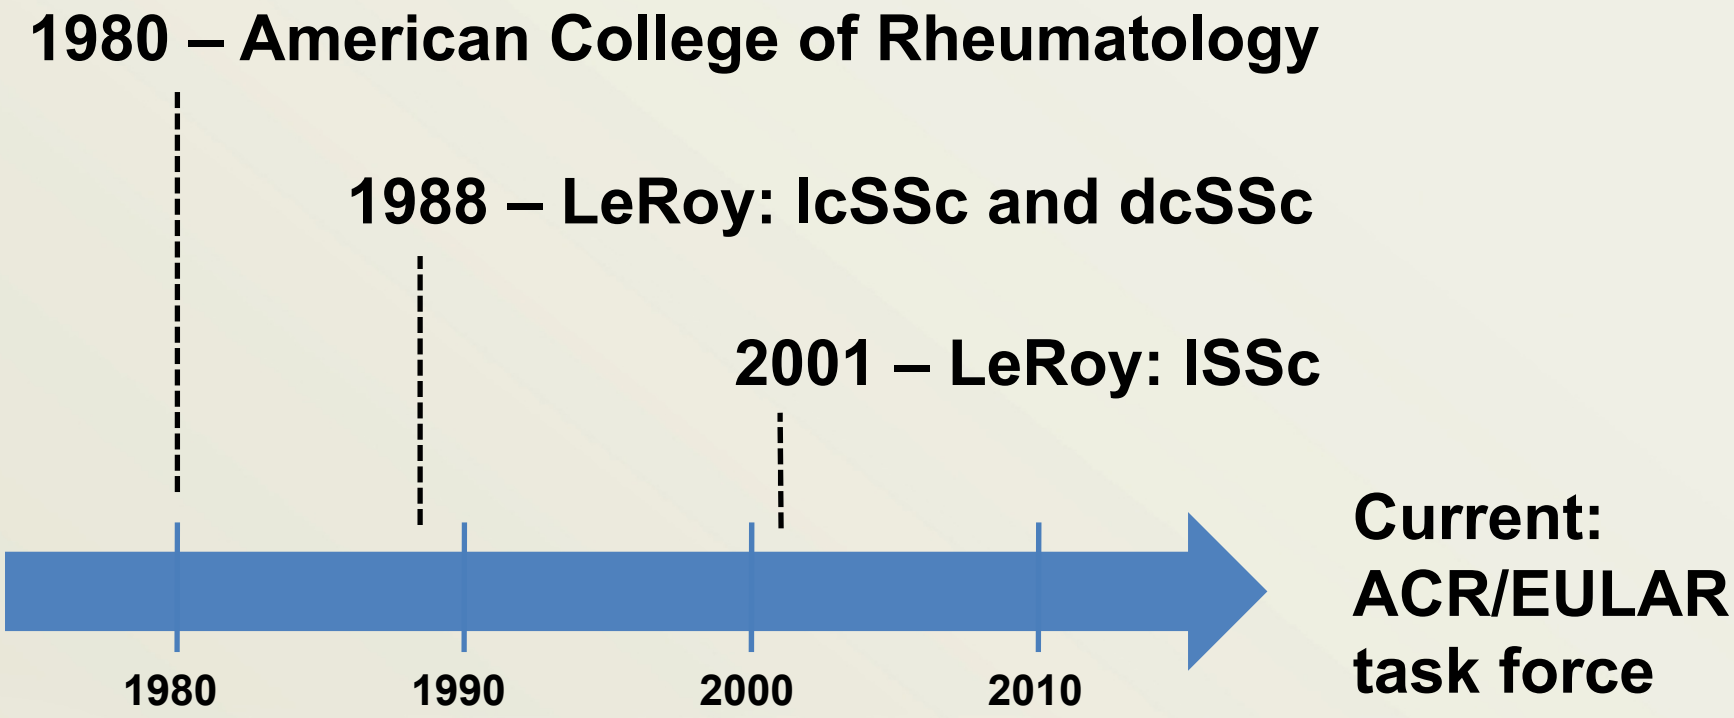
© 2013 ACR / EULAR

Why do we need SSc classification criteria?

1. To enroll SSc patients in studies (i.e., meeting classification criteria)
2. To differentiate SSc from other mimickers
3. To help to understand pathophysiology, subsets of patients with various features

© 2013 ACR / EULAR

Classification schemes – Overview



© 2013 ACR / EULAR

Which patient(s) meet the 1980 ACR SSc classification criteria?

1. Sclerodactyly, Raynaud's, positive anti-centromere, pulmonary arterial hypertension
2. Sclerodactyly, GERD, dilated esophagus, dysphagia RNA polymerase III, Scleroderma renal crisis
3. Sclerodactyly, Raynaud's, anti-centromere, dysphagia, dilated nailfold capillaries, calcinosis
4. Modified Rodnan skin score of 20 including finger involvement
5. Modified Rodnan skin score of 20 and no finger involvement ever, no Raynaud's Phenomenon and negative ANA

Subcommittee for Scleroderma Criteria of the American Rheumatism Association Diagnostic and Therapeutic Criteria Committee. *Arthritis Rheum* 1980; 23:581-90

© 2013 ACR / EULAR

Which patient(s) meet the 1980 ACR SSc classification criteria?

1. Sclerodactyly, Raynaud's, positive anti-centromere, pulmonary arterial hypertension **NO**
2. Sclerodactyly, GERD, dilated esophagus, dysphagia RNA polymerase III, Scleroderma renal crisis **NO**
3. Sclerodactyly, Raynaud's, anti-centromere, dysphagia, dilated nailfold capillaries, calcinosis **NO**
4. Modified Rodnan skin score of 20 including finger involvement
5. Modified Rodnan skin score of 20 and no finger involvement ever, no Raynaud's Phenomenon and negative ANA **NO**

Subcommittee for Scleroderma Criteria of the American Rheumatism Association Diagnostic and Therapeutic Criteria Committee. *Arthritis Rheum* 1980; 23:581-90

© 2013 ACR / EULAR

1980 ACR Scleroderma Classification Criteria

- **Major criterion:** proximal cutaneous sclerosis/skin thickening (non-pitting) proximal to the MCPs (metacarpophalangeal joints), affecting other parts of the body
  - usually bilateral, symmetrical, and almost always including sclerodactyly
  - **The major criterion is sufficient.**
- **Minor criteria: 2 or 3 are needed if no major criterion:**
  - sclerodactyly
  - digital pitting scars of fingertips or loss of substance of the distal finger pad
  - bibasalar pulmonary fibrosis

---

1 major criterion or ≥ 2 minor criteria were found in 97% of definite SSc cases (sensitivity 97%) but in only 2% of the comparison patients (specificity 98%)

Subcommittee for Scleroderma Criteria of the American Rheumatism Association Diagnostic and Therapeutic Criteria Committee. *Arthritis Rheum* 1980; 23:581-90.

© 2013 ACR / EULAR

What are the limitations of the 1980 ACR classification criteria for SSc?

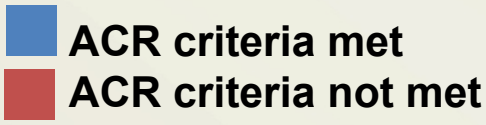
1. They don't classify some of those with limited cutaneous SSc
2. They don't always classify early SSc
3. They don't include antibodies that are common in SSc such as anti-centromere
4. They don't include nailfold changes that could help differentiate SSc from primary Raynaud's Phenomenon (RP)

Subcommittee for Scleroderma Criteria of the American Rheumatism Association Diagnostic and Therapeutic Criteria Committee. *Arthritis Rheum* 1980; 23:581-90

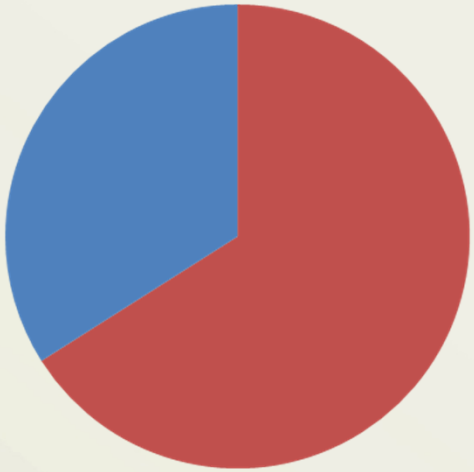
© 2013 ACR / EULAR

Limitations of the 1980 ACR Scleroderma classification

- Pittsburgh cohort of 639 patients with SSc[1]
  - 20% of limited SSc patients did not meet ACR criteria



- French Canadian cohort of 259 patients with SSc[2]
  - 66% of limited SSc patients did not meet ACR criteria



- **10 to 20% of limited SSc patients do not meet criteria for SSc[3]**
- Many SSc patients diagnosed by expert clinicians would be excluded based on ACR criteria

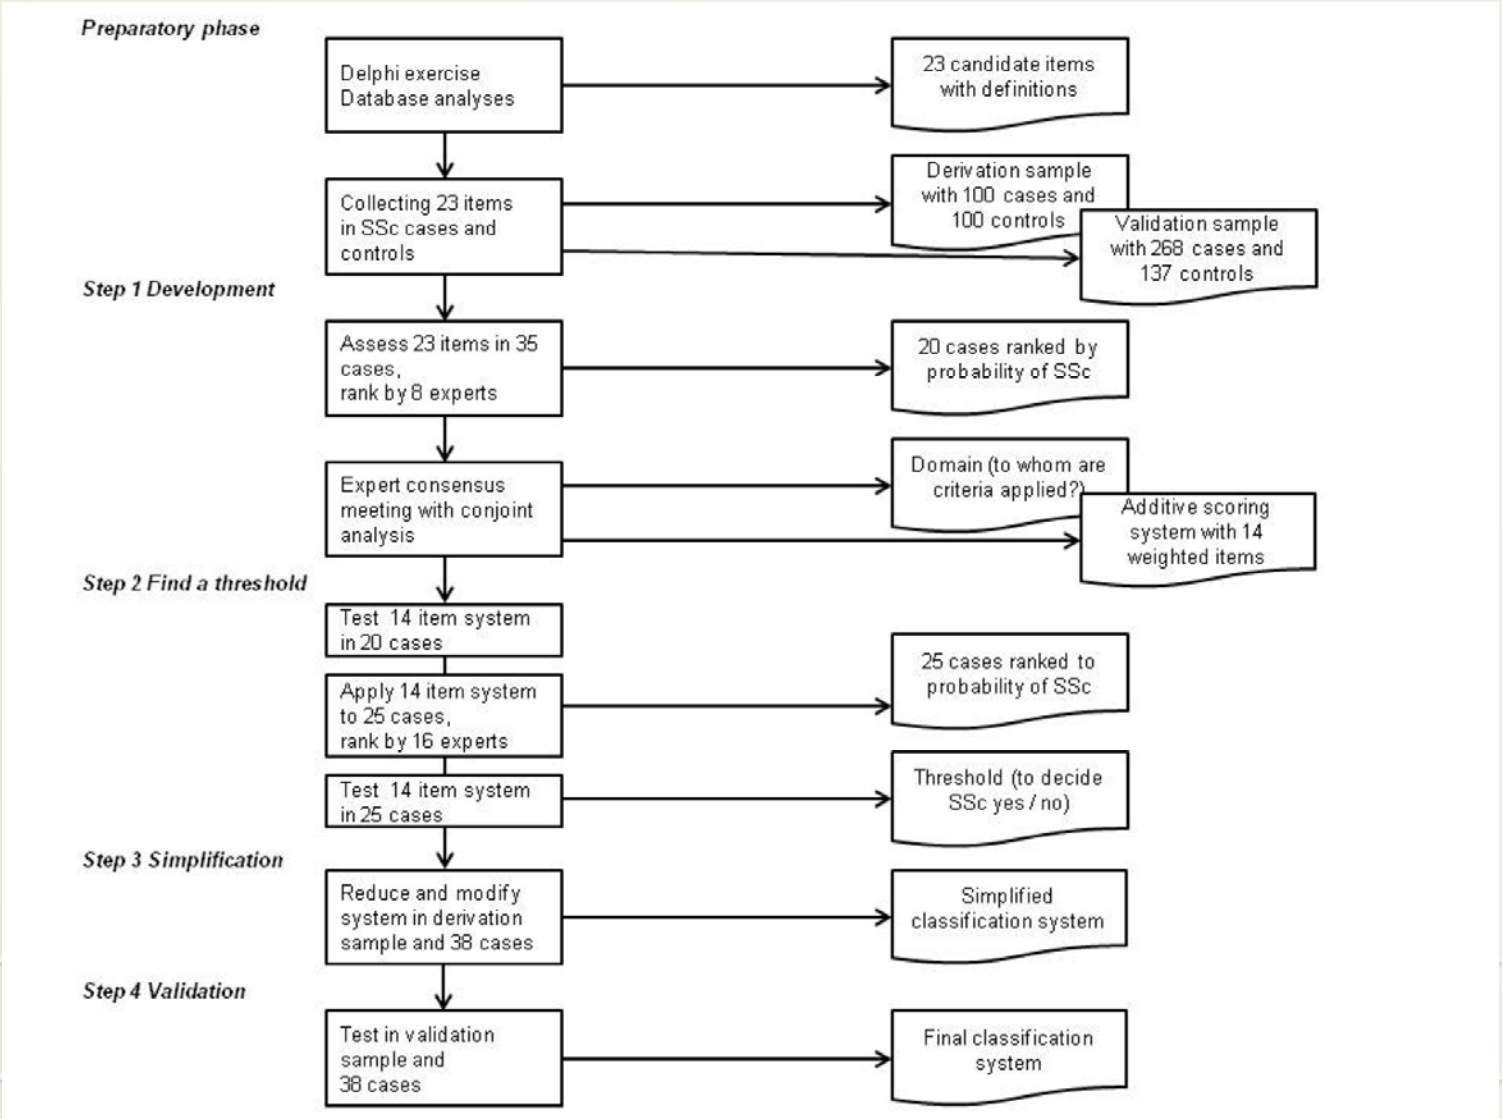
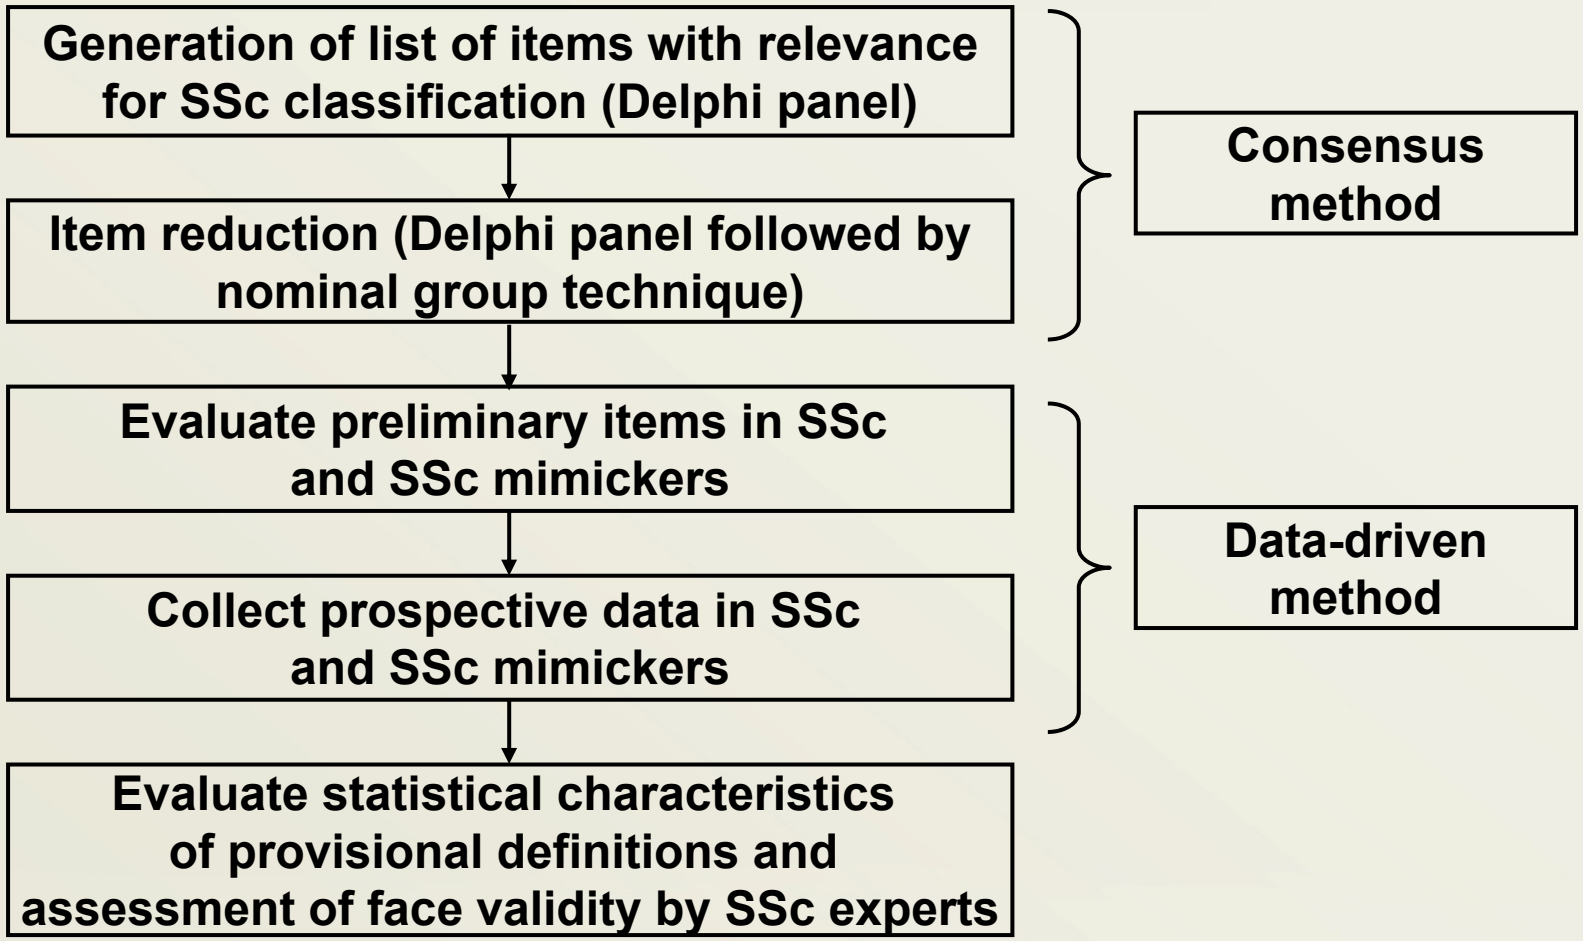
Overview of the ACR / EULAR SSc Classification Criteria Development



Preparatory phase
Delphi exercise
Database analyses
23 candidate items with definitions
Collecting 23 items in SSc cases and controls
Derivation sample with 100 cases and 100 controls
Validation sample with 268 cases and 137 controls
Step 1 Development
Assess 23 items in 35 cases, rank by 8 experts
20 cases ranked by probability of SSc
Expert consensus meeting with conjoint analysis
Domain (to whom are criteria applied?)
Additive scoring system with 14 weighted items
Step 2 Find a threshold
Test 14 item system in 20 cases
Apply 14 item system to 25 cases, rank by 16 experts
25 cases ranked to probability of SSc
Test 14 item system in 25 cases
Threshold (to decide SSc yes / no)
Step 3 Simplification
Reduce and modify system in derivation sample and 38 cases
Simplified classification system
Step 4 Validation
Test in validation sample and 38 cases
Final classification system

Reclassification of SSc by the ACR / EULAR Task Force



Generation of list of items with relevance for SSc classification (Delphi panel)
Item reduction (Delphi panel followed by nominal group technique)
Evaluate preliminary items in SSc and SSc mimickers
Collect prospective data in SSc and SSc mimickers
Evaluate statistical characteristics of provisional definitions and assessment of face validity by SSc experts
Consensus method
Data-driven method

SSc mimickers = eosinophilic fasciitis, generalised morphea, other connective tissue disease, scleromyxedema, etc.

© 2013 ACR / EULAR

Delphi results: Items to be tested for the new ACR / EULAR SSc criteria

Item	Appropriateness score* (median)	TOP score	Rank
Positive antitopoisomerase I	9	73%	1
Presence of scleroderma	9	70%	2
Abnormal nailfold capillary pattern	9	67%	3
Positive anticentromere	9	62%	4
Positive anti-RNA polymerase III	8	43%	5
Finger tip ulcers or pitting scars	8	34%	6
Raynaud's phenomenon	7	33%	7
Interstitial lung disease/pulmonary fibrosis	7	28%	8
Renal crisis	8	27%	9

*Scored from 1 to 9, with a higher score denoting greater appropriateness for the classification of SSc

Fransen J, et al. Arthritis Care Res (Hoboken). 2012 Mar;64(3):351-7.

DATA driven validation of top SSc items for criteria from DELPHI exercise

Criterion	Pooled mean OR (95% CrI)	Empiric ranking	Expert based ranking
Renal crisis	NC	1[ab]	9
Digital pulp loss or acro-osteolysis	NC	1[ab]	13[b]
Scleroderma	426.7 (256.5, 691.2)	2	1
Telangiectasia	91.4 (57.6, 154.5)	3	11
Anti-RNA polymerase III antibody	75.4 (13.2, 312.6)	4	6
Puffy fingers	34.9 (24.0, 49.2)	5	12
Finger or wrist flexion contracture	29.0 (17.8, 46.2)	6	19
Tendon or bursal friction rubs	26.81 (2.4, 91.9)	7	10
Anti-topoisomerase-1 antibody	24.9 (12.7, 48.0)	8	2
Raynaud's phenomenon	24.1 (15.3, 37.5)	9	7
Finger tip ulcers or pitting scars	19.3 (12.7, 28.8)	10	5
Anti-centromere antibody	13.8 (9.0, 21.0)	11	3
Abnormal nailfold capillary pattern	10.4 (6.9, 15.1)	12	4
Gastro-esophageal reflux disease	7.8 (6.1, 10.0)	13	17
Antinuclear antibody	6.06 (4.1, 8.8)	14	13[b]
Calcinosis	6.05 (3.4, 10.5)	15	18
Dysphagia	5.7 (4.2, 7.7)	16	19
Esophageal dilatation	5.6 (2.9, 10.2)	17	14
Interstitial lung disease	4.5 (3.4, 5.8)	18	8
Anti-PM-SCL antibody	2.4 (1.9, 7.1)	19	20[b]
Pulmonary arterial hypertension	1.2 (0.9, 1.5)	20	15
Carbon monoxide diffusion capacity (DLCO)	1.5 (1.1, 2.0)	21	16
Forced vital capacity (FVC)	0.9 (0.6, 1.3)	22	20[b]

NC= Not Calculable

1. These criteria are applicable to any patient considered for inclusion in a SSc study.
2. These criteria are **not applicable** to patients having a systemic sclerosis-like disorder better explaining their manifestations, such as: nephrogenic sclerosing fibrosis, scleredema diabeticorum, scleromyxedema, erythromyalgia, porphyria, lichen sclerosis, graft versus host disease, and diabetic chierarthropathy. Patients with '***Skin thickening sparing the fingers'*** also are not classified as having SSc.

Items	**Sub-items**	**Weight / Score**
Skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints		9
Skin thickening of the fingers *(only count the highest score)*	Puffy fingers	2
	Whole Finger, distal to MCP	4
Finger tip lesions	Digital Tip Ulcers	2
(only count the highest score)	Pitting Scars	3
Telangiectasia		2
Abnormal nailfold capillaries		2
Pulmonary arterial hypertension and/or Interstitial lung Disease		2
Raynaud's phenomenon		3
Scleroderma related antibodies (any of anti-centromere, anti-topoisomerasel [anti-ScL 70], anti-RNA polymerase III)		3
	TOTAL SCORE^:	

Patients having a total score of <u>9 or more</u> are being classified as having definite systemic sclerosis. ^ Add the maximum weight (score) in each category to calculate the total score.

Sensitivity and Specificity on ACR-EULAR Classification Criteria for SSc

	Derivation sample (N=200)		Validation sample (N=405)	
	Sensitivity (95% CI)	Specificity (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)
1980 ARA SSc Criteria	.80 (.72-.87)	.77 (.68-.84)	.75 (.70-.80)	.72 (.64-.79)
2001 LeRoy and Medsger criteria	.76 (.68-.84)	.69 (.68-.84)	.75 (.70-.80)	.78 (.70-.85)
2013 SSc Criteria	.95 (.90-.98)	.93 (.86-.97)	.91 (.87-.94)	.92 (.86-.96)

© 2013 ACR / EULAR

Item	Definition
Skin thickening	Skin thickening or hardening not due to scarring after injury, trauma, etc.
Puffy fingers	Swollen digits - a diffuse, usually nonpitting increase in soft tissue mass of the digits extending beyond the normal confines of the joint capsule. Normal digits are tapered distally with the tissues following the contours of the digital bone and joint structures. Swelling of the digits obliterates these contours. Not due to other reasons such as inflammatory dactylitis.
Finger tip ulcers or pitting scars	Ulcers or scars distal to or at the PIP joint not thought to be due to trauma. Digital pitting scars are depressed areas at digital tips as a result of ischemia, rather than trauma or exogenous causes.
Telangiectasia	Telangiectasia(e) in a scleroderma like pattern are round and well demarcated and found on hands, lips, inside of the mouth, and/or large matt-like telangiectasia(e). Telangiectasiae are visible macular dilated superficial blood vessels; which collapse upon pressure and fill slowly when pressure is released; distinguishable from rapidly filling spider angiomas with central arteriole and from dilated superficial vessels.
Abnormal nailfold capillary pattern consistent with SSc	Enlarged capillaries and/or capillary loss with or without peri-capillary hemorrhages at the nailfold and may be seen on the cuticle.
Pulmonary arterial hypertension	Pulmonary arterial hypertension diagnosed by right heart catheterization according to standard definitions.
Interstitial lung disease	Pulmonary fibrosis on HRCT or chest radiograph, most pronounced in the basilar portions of the lungs, or presence of 'Velcro' crackles on auscultation not due to another cause such as congestive heart failure.
Raynaud's phenomenon	Self report or reported by a physician with at least a two-phase color change in finger(s) and often toe(s) consisting of pallor, cyanosis and/or reactive hyperemia in response to cold exposure or emotion; usually one phase is pallor.
Scleroderma specific antibodies	Anti-centromere antibody or centromere pattern on antinuclear antibody (ANA) testing; anti-topoisomerase I antibody (also known as anti-Scl70 antibody); or anti-RNA polymerase III antibody. Positive according to local laboratory standards.

Defini-tions of terms

Classification criteria

- They are not diagnostic criteria but hopefully are close
- Thus early patients may not be classified
- Classification criteria do not equal diagnositic criteria, so it is possible that some patients may be diagnosed with SSc but don't meet the ACR / EULAR SSc classification criteria

© 2013 ACR / EULAR

Use of the ACR / EULAR SSc classification criteria

- **Exclusion criteria**
  - You know there is a different disease
  - Absence of sclerodactyly (ever) if skin involvement is elsewhere
- **Absolute inclusion criterion**
  - Scleroderma skin involvement with sclerodactyly and contiguous skin involvement proximal to the MCPs

© 2013 ACR / EULAR

Caveats for ACR / EULAR SSc classification criteria

- Mark highest score in each category
- Not all centers have access to RNApolymerase III Ab
- Don’t apply criteria if you don’t think patient has SSc or have a better explanation
  - Such as generalized morphea
- You can have more than one connective tissue disease (CTD) so a patient can have an overlap with SSc as one of the diseases and some patients with mixed connective tissue disease may be classified with SSc

© 2013 ACR / EULAR

Conclusions

- There is a need to effectively classify SSc patients
- Classification systems have evolved over the years with advancing technology
  - Capillaroscopy, autoantibodies, new methodologies
- Patients can be classified with more than one disease with the ACR / EULAR SSc classification criteria (i.e., overlaps)
- You have to do some math!
- Current classification includes more patients who would not have been classified by previous criteria

© 2013 ACR / EULAR

Conclusions about 2013 ACR/EULAR SSc classification criteria

- Items have good face validity
- Items have good discriminant validity
- Items have good construct validity
- The sensitivity and specificity of the ACR/EULAR SSc classification criteria are better than previous criteria

© 2013 ACR / EULAR

Using the 2013 ACR / EULAR SSC Classification Criteria

- Apply the criteria for SSc, if appropriate

© 2013 ACR / EULAR

1. These criteria are applicable to any patient considered for inclusion in a SSc study.
2. These criteria are **not applicable** to patients having a systemic sclerosis-like disorder better explaining their manifestations, such as: nephrogenic sclerosing fibrosis, scleredema diabeticorum, scleromyxedema, erythromyalgia, porphyria, lichen sclerosis, graft versus host disease, and diabetic chierarthropathy. Patients with '***Skin thickening sparing the fingers'*** also are not classified as having SSc.

Items	**Sub-items**	**Weight / Score**
Skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints		9
Skin thickening of the fingers *(only count the highest score)*	Puffy fingers	2
	Whole Finger, distal to MCP	4

Early symptoms of SSc

- Raynaud's phenomenon
  - May precede skin changes and visceral disease by several years especially in limited SSc
  - In dcSSc, RP may begin shortly after or coincident with the onset of skin disease
  - SSc patients may have less hyperaemia than in primary Raynaud's due to structural vasculopathy in SSc
- Puffy fingers may be the presenting sign in dcSSc
- Malaise, fatigue, arthralgia, myalgia
- Gastroesophageal symptoms or dyspnoea may be the presenting symptoms

Guidelines

BSR and BHPR guideline for the treatment of systemic sclerosis

Christopher P. Denton[1], Michael Hughes[2], Nataliya Gak[1], Josephine Vila[3], Maya H. Buch[4], Kuntal Chakravarty[1], Kim Fligelstone[1], Luke L. Gompels[5], Bridget Griffiths[3], Ariane L. Herrick[2], Jay Pang[6], Louise Parker[7], Anthony Redmond[4], Jacob van Laar[8], Louise Warburton[9] and Voon H. Ong[1] on behalf of the BSR and BHPR Standards, Guidelines and Audit Working Group

Key words: scleroderma, systemic sclerosis, management, Raynaud's phenomenon, lung fibrosis, pulmonary hypertension, digital ulcers

GUIDELINES

Executive Summary

Scope and purpose

SSc is a complex, multi-organ disease that requires a comprehensive multidisciplinary guideline. This is a short summary of the guideline, which is available in full as supplementary material at *Rheumatology* Online. Each recommendation is graded for level of evidence (I-IV) and strength (A-D).

Eligibility and exclusion criteria

Patients are classified as having SSc based on current classification criteria (ACR/EULAR 2013 [1]). Other scleroderma spectrum diseases are not included in this document.

NICE has accredited the process used by the BSR to produce its treatment of systemic sclerosis guidance. Accreditation is valid for 5 years from 10 June 2013. More information on accreditation can be viewed at www.nice.org.uk/accreditation. For full details on our accreditation visit: www.nice.org.uk/accreditation.

Part A: general approach to SSc management

Figure 1 summarizes a general approach to management of SSc.

Importance of early diffuse SSc: current priorities and approach

Management of early diffuse cutaneous SSc (dcSSc) should occur within the framework of a multidisciplinary team.

Recommendations in management of early SSc

(i) Early recognition and diagnosis of dcSSc is a priority, with referral to a specialist SSc centre (III, C).

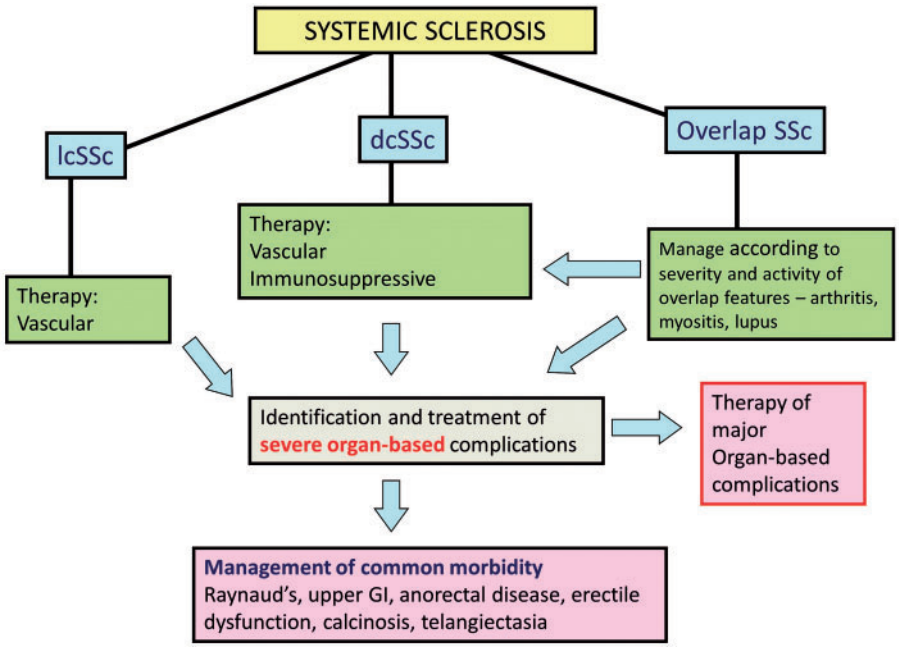
Fig. 1 Overview of management of SSc



The principles of current management of SSc are summarized. Once a confirmed diagnosis is established, all patients can be designated as either lcSSc or dcSSc subset based upon the extent of skin thickening. Proximal skin involvement, involving skin of trunk or proximal limbs, is designated diffuse. Cases with overlap disease should be identified so that overlap features may be treated concurrently with SSc. All patients require symptomatic treatment, and both limited and diffuse cases should be treated for vascular manifestations. Active, early dcSSc requires immunosuppressive treatment. In all cases of SSc, vigilant follow-up to determine significant organ-based complications is mandatory. dcSSc: diffuse cutaneous SSc; lcSSc: limited cutaneous SSc; GI: gastrointestinal.

(ii) Patients with early dcSSc should be offered an immunosuppressive agent: MTX, MMF or i.v. CYC (III/C), although the evidence base is weak. Some patients might later be candidates for autologous haemopoietic stem cell transplant (ASCT; see below).
(iii) D-Pen is not recommended (IIa/C).
(iv) ASCT may be considered in some cases, particularly where there is risk of severe organ involvement, balancing concerns about treatment toxicity (IIa/C).
(v) Skin involvement may be treated with either MTX (II, B) or MMF (III, C). Other options include CYC (III, C), oral steroid therapy (in as low a dose as possible to suppress symptoms, and with close monitoring of renal function; III, C) and possibly rituximab (III, C).
(vi) AZA or MMF should be considered after CYC to maintain improvement in skin sclerosis and/or lung function (III, C).

Part B: key therapies and treatment of organ-based disease

RP and digital ulcers

RP is almost universal and can be treated by vasodilators, but benefit must be balanced against side-effects. Around half of patients with SSc report a history of digital ulceration that reflects more structural vasculopathy. Severe digital ulcers (DUs) are those causing or threatening tissue destruction or when three or more occur in 1 year. These should be considered for advanced therapy, such as sildenafil, iloprost or bosentan [2].

Recommendations for RP in SSc

(i) First-line treatments are calcium channel blockers (Ia, A) and angiotensin II receptor antagonists (Ib, C).
(ii) Other treatments that may be considered are: selective serotonin reuptake inhibitors, α-blockers and statin therapy (III, C).
(iii) Phosphodiesterase type 5 inhibitors are being used increasingly for SSc-related RP (IIa, C).
(iv) Intravenous prostanoid (e.g. iloprost; Ia, B) and digital (palmar) sympathectomy (with or without botulinum toxin injection) should be considered in severe and/or refractory cases (III, D).

Recommendations for DUs in SSc

(i) DUs require integrated management by a multidisciplinary team; management includes local and systemic treatment (III, C).
(ii) Oral vasodilator treatment should be optimized, analgesia optimized and any infection promptly treated (III, C).

Downloaded from https://academic.oup.com/rheumatology/article/55/10/1906/2196591 by guest on 03 February 2023

(iii) Sildenafil should now be used before considering i.v. prostanoids and bosentan, in line with the current National Health Service (NHS) England Clinical Commissioning policy [3] (I, A).
(iv) In severe active digital ulceration, patients should receive i.v. prostanoid (Ia, B). In patients with recurrent, refractory DUs, a phosphodiesterase type 5 inhibitor (IIa, B) or i.v. prostanoid (Ia, B) and an endothelin receptor antagonist (including bosentan; Ia, B) should be considered.
(v) Digital (palmar) sympathectomy (with or without botulinum toxin injection) may also be considered in severe and/or refractory cases (III, D).

Lung fibrosis

Up to 80% of SSc patients will develop interstitial lung disease, but this may be mild and stable. Immunosuppression should be considered when extensive or progressive disease is confirmed.

Recommendations for lung fibrosis in SSc

(i) All SSc cases should be evaluated for lung fibrosis. Treatment is determined by the extent and severity and the likelihood of progression to severe disease (I, A).
(ii) CYC by i.v. infusion is recommended (I, A/B), and MMF may also be used as an alternative or after CYC (II, B).

Pulmonary arterial hypertension

For patients living in England, treatments are initiated through a designated Pulmonary Hypertension Centre (see NHS England A11/S/a) according to the national commissioning policy for treatment of pulmonary arterial hypertension (PAH; NHS England/A11/P/b and NHS Commissioning Board (NHSCB)/A11/P/a), reflecting expert recommendations [4].

Recommendations for PAH in SSc

(i) Diagnosis should be based upon results of full evaluation of PAH, including right heart catheterization and evaluation of concomitant SSc-related cardiac or lung disease (I, A).
(ii) Therapies licensed for PAH should be used in the UK Pulmonary Hypertension Centres, taking account of the agreed commissioning policies (I, A/B).

Gut disease

Gastro-oesophageal reflux is near universal and needs treatment. Other gastrointestinal (GI) manifestations include constipation, bloating, small intestinal bacterial overgrowth, altered bowel habit and anorectal incontinence (overall management covered elsewhere [5]).

Recommendations for GI manifestations in SSc

The following therapeutic approaches and drugs are considered by experts to be of value in treatment of GI tract complications of SSc.

(i) Proton pump inhibitors and histamine H2 receptor antagonists are recommended for treatment of gastro-oesophageal reflux and dysphagia and may require long-term administration (III, C).
(ii) Prokinetic dopamine antagonists may be used for dysphagia and reflux (III, C).
(iii) Parenteral nutrition should be considered for patients with severe weight loss refractory to enteral supplementation (III, C).
(iv) Intermittent broad-spectrum oral antibiotics (e.g. ciprofloxacin) are recommended for intestinal overgrowth, and rotational regimes may be helpful (III, C).
(v) Anti-diarrhoeal agents (e.g. loperamide) or laxatives may be used for symptomatic management of diarrhoea or constipation that often alternate as clinical problems (III, C).

Renal complications

SSc renal crisis (SRC) causes severe hypertension and acute kidney injury and without treatment is often lethal. It affects 5–10% of SSc patients, predominantly the diffuse subset.

Recommendations for treatment of SRC

(i) Patients at risk of SRC should be followed closely and their blood pressure monitored at least weekly (III, C).
(ii) Prompt recognition of SRC and initiation of therapy with an angiotensin-converting enzyme inhibitor offers the best opportunity for a good outcome (III, C).
(iii) Other anti-hypertensive agents may be considered for management of refractory hypertension in conjunction with an angiotensin-converting enzyme inhibitor in SRC (III, C).

Cardiac disease

Clinically evident cardiac involvement includes diastolic or systolic heart failure, arrhythmia and conduction disturbances and has a significant mortality.

Recommendations for treatment of cardiac manifestations of SSc

Although the published evidence base is limited, experts have recommended the following treatment approach for cardiac complications of SSc.

Systolic heart failure

(i) Consider immunosuppression with or without a pacemaker (IV, D).
(ii) Consider the potential benefit of an implantable cardioverter defibrillator (III, D).
(iii) Angiotensin-converting enzyme inhibitors and carvedilol. Selective β-blockers may be considered, but consider aggravation of RP (IV, D).

Diastolic heart failure with preserved left ventricular ejection fraction

(i) Diuretics, including spironolactone and furosemide (IV, D).

Downloaded from https://academic.oup.com/rheumatology/article/55/10/1906/2196591 by guest on 03 February 2023

(ii) Calcium channel blockers have been shown to reduce the frequency of systolic heart failure in SSc with investigational evidence of cardiac abnormalities (III, D).

Skin manifestations

Treatment of skin thickening, assessed by modified Rodnan skin score, is central to management of dcSSc treatment, and pruritus is common and troublesome in early stage disease.

Recommendations for skin manifestations in SSc

(i) Practical approaches to ensure adequately moisturized skin are essential, especially moisturizers that are lanolin based (III, C).
(ii) Antihistamines are often used for itch (III, C).
(iii) Current treatment options for telangiectasia include skin camouflage and laser or intense pulsed light therapy (III, C).

Calcinosis in SSc

There is a very limited evidence base (mainly case reports and small series) to guide clinicians on the management of calcinosis in patients with SSc.

Recommendations for treatment of calcinosis in SSc

(i) Calcinosis complicated by infection should be recognized early and treated with appropriate antibiotic therapy (III, D).
(ii) Surgical intervention should be considered for severe, refractory calcinosis, which is severely impacting upon functional ability and quality of life (III, D).

Musculoskeletal manifestations

Musculoskeletal involvement includes tendinopathy, joint contractures and, in some cases, overlap arthritis.

Recommendations for musculoskeletal manifestations in SSc

(i) Musculoskeletal manifestations of SSc may benefit from immunomodulatory treatments given for other complications, such as skin disease (III, C).
(ii) When arthritis or myositis is more severe, generally in the context of an overlap SSc syndrome, management is in line with similar clinical conditions occurring outside the context of SSc (III, C).

ASCT as a treatment for poor prognosis early dcSSc

Haematopoietic stem cell transplant registry data, several case reports and pilot studies in the USA and Europe in dcSSc demonstrated a rapid clinical improvement, but with important treatment-related mortality [6].

Recommendation for ASCT in SSc

(i) Current evidence supports use of ASCT in poor-prognosis diffuse SSc where patients do not have severe internal organ manifestations that render this treatment option highly toxic (Ib, B).

Non-drug interventions

Although the evidence base is limited, non-drug interventions may have merit and are well tolerated.

Recommendation for non-drug interventions in SSc

(i) Specialist experience of SSc cases is likely to make non-drug interventions more effective, and these approaches are popular with patients and can be expected to impact positively on the disease. More research is needed in this area (III, D).

Part C: service organization and delivery within NHS England

SSc should be diagnosed promptly, investigated appropriately and managed within an integrated system of primary, secondary and tertiary level care.

Objective. **The 1980 American College of Rheumatology (ACR) classification criteria for systemic sclerosis (SSc) lack sensitivity for early SSc and limited cutaneous SSc. The present work, by a joint committee of the ACR and the European League Against Rheumatism (EULAR), was undertaken for the purpose of developing new classification criteria for SSc.**

Methods. **Using consensus methods, 23 candidate items were arranged in a multicriteria additive point system with a threshold to classify cases as SSc. The classification system was reduced by clustering items and simplifying weights. The system was tested by 1) determining specificity and sensitivity in SSc cases and controls with scleroderma-like disorders, and 2) validating against the combined view of a group of experts on a set of cases with or without SSc.**

Results. **It was determined that skin thickening of the fingers extending proximal to the metacarpophalangeal joints is sufficient for the patient to be classified as having SSc; if that is not present, 7 additive items apply, with varying weights for each: skin thickening of the fingers, fingertip lesions, telangiectasia, abnormal nailfold capillaries, interstitial lung disease or pulmonary arterial hypertension, Raynaud's phenomenon, and SSc-related autoantibodies. Sensitivity and specificity in the validation sample were, respectively, 0.91 and 0.92 for the new classification criteria and 0.75 and 0.72 for the 1980 ACR classification criteria. All selected cases were classified in accordance with consensus-based expert opinion. All cases classified as SSc accord-**

ing to the 1980 ACR criteria were classified as SSc with the new criteria, and several additional cases were now considered to be SSc.

***Conclusion*. The ACR/EULAR classification criteria for SSc performed better than the 1980 ACR criteria for SSc and should allow for more patients to be classified correctly as having the disease.**

Introduction

Systemic sclerosis (SSc; scleroderma) is a heterogeneous disease whose pathogenesis is characterized by 3 hallmarks: small vessel vasculopathy, production of autoantibodies, and fibroblast dysfunction leading to increased deposition of extracellular matrix (1). The clinical manifestations and the prognosis of SSc vary, with the majority of patients having skin thickening and variable involvement of internal organs. Subsets of SSc can be discerned, i.e., limited cutaneous SSc, diffuse cutaneous SSc, and SSc without skin involvement (1).

In the absence of a diagnostic test proving the absence or presence of SSc, several sets of classification criteria have been developed (2–6). The purpose of classification criteria is to enroll, in research studies, patients who in fact have the disease as determined using a uniform definition (7). Classification criteria are not synonymous with diagnostic criteria but will almost always mirror the list of criteria that are used for diagnosis (7). However, classification criteria generally are more standardized and less inclusive than physician diagnosis.

The current standard classification criteria for SSc are the 1980 preliminary criteria for the classification of systemic sclerosis (scleroderma), developed by the American College of Rheumatology (ACR) (2–4,8). These classification criteria were developed using patients with longstanding SSc. As a consequence, patients with early SSc and ~20% of patients with limited cutaneous disease do not meet the criteria and are excluded from clinical studies (1,9,10). Since the development of the 1980 criteria, knowledge regarding SSc-related autoantibodies has improved (11–13). In addition, characteristic nailfold capillary changes have been found to be associated with SSc, and nailfold capillaroscopy is widely accepted as a diagnostic tool (10,14–17). In 1988, LeRoy et al proposed new criteria that included clinical features, autoantibodies, and capillaroscopy results, highlighting the differences between the 2 main SSc subsets (11). In 2001, LeRoy and Medsger proposed to revise the classification criteria to include "early" SSc, using nailfold capillary pattern and SSc-related autoantibodies (6). It also has been demonstrated that the addition of nailfold capillary abnormalities and telangiectasias to the ACR SSc criteria improves their sensitivity (9,18).

Because of the insufficient sensitivity of the 1980 criteria and advances in knowledge about SSc, the ACR and the European League Against Rheumatism (EULAR) established a committee to provide a joint proposal for new classification criteria for SSc. The aims were to develop criteria that 1) encompass a broader spectrum of SSc including patients whose disease is in the early stage as well as those in the late stage; 2) include vascular, immunologic, and fibrotic manifestations; 3) are feasible to use in daily clinical practice; and 4) are in accordance with criteria used for diagnosis of SSc in clinical practice (7). These criteria are intended to be used by rheumatologists, researchers, national and international drug agencies, pharmaceutical companies, or any others involved in studies of SSc. Our objective was to develop a set of criteria that would enable identification of individuals with SSc for inclusion in clinical studies, being more sensitive and specific than previous criteria.

Methods

Overview. The development and testing of the classification system for SSc was based on both data and expert clinical judgment. First, candidate items for the classification criteria were generated using consensus methods and evaluated using existing databases (19,20). Second, multicriteria decision analysis was used to reduce the number of candidate criteria and assign preliminary weights (21). The classification system was repeatedly tested and adapted using prospectively collected SSc cases and non-SSc controls, and compared against expert clinical judgment. Third, the classification criteria were tested in a validation cohort and tested against preexisting criteria sets.

Item generation and reduction. One hundred sixty-eight candidate criteria were identified through 2 Delphi exercises. A 3-round Delphi exercise and a face-to-face consensus meeting using nominal group technique facilitated reduction of the 168 items to 23 (19). Using a random sample of existing databases (SSc [n = 783] and control patients with diseases similar to SSc [n = 1,071], all based on physician diagnosis), the candidate criteria were found to have good discriminative validity (20).

Item reduction and weighting. *Draft classification system.* A face-to-face meeting of 4 European and 4 North American SSc experts was held to further reduce items and assign preliminary weights using multicriteria decision analysis. The number of experts was limited in advance to 8, and they were invited based on geographic representation, knowledge from a scientific and a practical diagnostic viewpoint, and availability. At the meeting, the experts determined by consensus to which cases the criteria should be and should not be

applied, and which items are sufficient to allow classification of a patient as having SSc (sufficient criteria). They then participated in a multicriteria decision analysis to further reduce the 23 items and assign preliminary weights (21). The experts were presented hypothetical pairs of cases with 2 of the 23 items at a time (e.g., Raynaud's phenomenon positive *and* abnormal nailfold capillaries absent versus Raynaud's phenomenon negative *and* abnormal nailfold capillaries present, all other manifestations being considered equal) and they were asked to individually vote electronically on which case of the pair was more likely to be SSc. The result of the votes was immediately presented. If there was no complete agreement among the experts, considerations were discussed and a second round of voting was conducted. As a result of the repeated choices between 2 alternative cases, items were ranked, and weights for the items were derived using 1000Minds decision-making software (21). Additional details about the methods are available in ref. 22.

Initial threshold identification. The committee prepared summaries of 45 SSc cases, with a concentration of cases that were difficult to classify. These were presented to 22 SSc experts who classified the cases as definite SSc or not. The draft classification system derived from the multicriteria decision analysis was applied to the 45 cases, resulting in a score for each case. The ranking of cases by the SSc experts and the ranking of cases based on the scores provided with the draft scoring system were examined. Higher scores in the scoring system were expected to relate to a higher probability that the experts would classify the case as SSc. Using these results, an initial threshold score for SSc was identified.

Reduction and testing of iterative changes. In the next step, the committee reduced the number of items, simplified the weights, and modified the threshold score. First, data on the candidate items were prospectively collected at 13 SSc centers in North America and 10 in Europe, using standardized case record forms. Data from 368 consecutive patients with SSc (diagnosis based on physician opinion) were collected, of whom half were to have had SSc for a maximum of 2 years (based on the time from the first non-Raynaud's symptom) in order to include early SSc. Data from 237 consecutive control patients with a scleroderma-like disorder (eosinophilic fasciitis [also called Shulman's disease or diffuse fasciitis with eosinophilia], scleromyxedema, systemic lupus erythematosus, dermatomyositis, polymyositis, primary Raynaud's phenomenon, mixed connective tissue disease, undifferentiated connective tissue disease, generalized morphea, nephrogenic systemic sclerosis, and diabetic cheiroarthropathy) were also collected. From these 605 patients a random sample of 100 SSc cases and 100 controls (50% from North America and 50% from Europe) was selected to form the derivation sample. The remaining 268 cases and 137 controls formed the validation sample. Institutional research ethics board approval was obtained for the collection of patient data.

The committee then met and made iterative changes to the draft system, which they continually applied in real time to the derivation cohort derived as described above. Using the derivation cohort, the scoring system was simplified by removing items that occurred with low frequency or were redundant, by aggregating similar items and then transforming the weights to obtain single digits. The preliminary score threshold was adjusted to account for the weight simplification. The impact of all proposed changes was evaluated by assessing changes to sensitivity and specificity of the criteria in the derivation cohort. The reference standard to test the sensitivity and specificity was the diagnosis by the SSc expert who submitted the case(s) and control(s).

At the same time, the changes in the classification system were also tested in 38 difficult-to-classify cases. Consequently, weights of some items were adjusted to align the scoring system with the reference standard formed by the opinions of the SSc experts as to which cases were to be classified as having SSc.

Validation. The final classification system was independently tested using the validation sample of SSc cases and controls. Sensitivity and specificity were calculated for the 1980 ACR preliminary classification criteria for SSc (3), the classification criteria proposed by LeRoy and Medsger in 2001 (6), and the newly developed classification criteria. Exact binomial confidence limits were calculated for sensitivity and specificity. The ACR criteria and LeRoy/Medsger criteria were compared with the new criteria using 2×2 tables with McNemar's chi-square test and continuity correction. The criteria sets were also tested separately using only the subgroup of patients with a disease duration of ≤ 3 years. Further, the classification system was validated against the expert consensus on the set of 38 selected cases.

Results

Draft classification system. The experts concluded that "skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints" was sufficient to classify a subject as having SSc. Further, patients with "skin thickening sparing the fingers" are classified as not having SSc. It was agreed that the criteria should be applied to any patient considered for inclusion in an SSc study, without further specifications. Items with relatively low weights were deleted, and items considered to be from a similar domain were clustered (e.g., fingertip lesions encompasses ulcers and pitting scars; lung involvement encompasses interstitial lung disease and pulmonary hypertension). Using conjoint analysis, the number of items was reduced from 23 to 14 and all items were assigned weights. The 14 resulting items (with weights) were as follows: bilateral skin thickening of the fingers (sclerodactyly) (weighted 14 if distal to a proximal interphalangeal joint only, 22 if whole finger), puffy fingers (weighted 5), fingertip lesions (weighted 16 if pitting scars or 9 if digital ulcers), finger flexion contractures (weighted 16), telangiectasia (weighted 10), abnormal nailfold capillaries (weighted 10), calcinosis (weighted 12), Raynaud's phenomenon (weighted 13), tendon or bursal friction rubs (weighted 21), interstitial lung disease/pulmonary fibrosis (weighted 14), pulmonary arterial hypertension (weighted 12), scleroderma renal crisis (weighted 11), esophageal dilation (weighted 7), and SSc-related autoantibodies (weighted 15 if anticentromere antibody pres-

Table 1. The American College of Rheumatology/European League Against Rheumatism criteria for the classification of systemic sclerosis (SSc)*

Item	Sub-item(s)	Weight/score†
Skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints *(sufficient criterion)*	–	9
Skin thickening of the fingers *(only count the higher score)*	Puffy fingers	2
	Sclerodactyly of the fingers (distal to the metacarpophalangeal joints but proximal to the proximal interphalangeal joints)	4
Fingertip lesions *(only count the higher score)*	Digital tip ulcers	2
	Fingertip pitting scars	3
Telangiectasia	–	2
Abnormal nailfold capillaries	–	2
Pulmonary arterial hypertension and/or interstitial lung disease *(maximum score is 2)*	Pulmonary arterial hypertension	2
	Interstitial lung disease	2
Raynaud's phenomenon	–	3
SSc-related autoantibodies (anticentromere, anti–topoisomerase I [anti–Scl-70], anti–RNA polymerase III) *(maximum score is 3)*	Anticentromere	3
	Anti–topoisomerase I	
	Anti–RNA polymerase III	

* These criteria are applicable to any patient considered for inclusion in an SSc study. The criteria are not applicable to patients with skin thickening sparing the fingers or to patients who have a scleroderma-like disorder that better explains their manifestations (e.g., nephrogenic sclerosing fibrosis, generalized morphea, eosinophilic fasciitis, scleredema diabeticorum, scleromyxedema, erythromyalgia, porphyria, lichen sclerosis, graft-versus-host disease, diabetic cheiroarthropathy).
† The total score is determined by adding the maximum weight (score) in each category. Patients with a total score of ≥ 9 are classified as having definite SSc.

Table 2. Definitions of items/sub-items in the American College of Rheumatology/European League Against Rheumatism criteria for the classification of systemic sclerosis (SSc)

Item	Definition
Skin thickening	Skin thickening or hardening not due to scarring after injury, trauma, etc.
Puffy fingers	Swollen digits—a diffuse, usually nonpitting increase in soft tissue mass of the digits extending beyond the normal confines of the joint capsule. Normal digits are tapered distally with the tissues following the contours of the digital bone and joint structures. Swelling of the digits obliterates these contours. Not due to other causes such as inflammatory dactylitis.
Fingertip ulcers or pitting scars	Ulcers or scars distal to or at the proximal interphalangeal joint not thought to be due to trauma. Digital pitting scars are depressed areas at digital tips as a result of ischemia, rather than trauma or exogenous causes.
Telangiectasia	Telangiectasiae are visible macular dilated superficial blood vessels, which collapse upon pressure and fill slowly when pressure is released. Telangiectasiae in a scleroderma-like pattern are round and well demarcated and found on hands, lips, inside of the mouth, and/or are large mat-like telangiectasiae. Distinguishable from rapidly filling spider angiomas with central arteriole and from dilated superficial vessels.
Abnormal nailfold capillary pattern consistent with systemic sclerosis	Enlarged capillaries and/or capillary loss with or without pericapillary hemorrhages at the nailfold. May also be seen on the cuticle.
Pulmonary arterial hypertension	Pulmonary arterial hypertension diagnosed by right-sided heart catheterization according to standard definitions.
Interstitial lung disease	Pulmonary fibrosis seen on high-resolution computed tomography or chest radiography, most pronounced in the basilar portions of the lungs, or occurrence of "Velcro" crackles on auscultation, not due to another cause such as congestive heart failure.
Raynaud's phenomenon	Self-reported or reported by a physician, with at least a 2-phase color change in finger(s) and often toe(s) consisting of pallor, cyanosis, and/or reactive hyperemia in response to cold exposure or emotion; usually one phase is pallor.
SSc-related autoantibodies	Anticentromere antibody or centromere pattern seen on antinuclear antibody testing, anti–topoisomerase I antibody (also known as anti–Scl-70 antibody), or anti–RNA polymerase III antibody. Positive according to local laboratory standards.

* Data were prospectively collected on 605 consecutive patients with systemic sclerosis (SSc) or a scleroderma-like disorder (see Methods); half of the SSc patients at each site were to have early SSc. A random sample of 100 SSc cases and 100 controls, 50% from North America and 50% from Europe, was selected to form the derivation sample, and the remaining patients formed the validation sample. Except where indicated otherwise, values are the number (%). IQR = interquartile range; PAH = pulmonary arterial hypertension; ILD = interstitial lung disease; MCP = metacarpophalangeal.

† Listed in order of frequency of occurrence in the SSc derivation sample.

ent, anticentromere pattern seen on antinuclear antibody testing, or anti–topoisomerase I [also called anti–Scl-70] or anti–RNA polymerase III present).

Initial threshold identification. Comparison of the case ranking from the scoring system and by the experts revealed that most of the experts (≥75%) considered the cases with a score of >55 (except for 1 case) to be SSc. Similarly, most experts (≥88%) considered cases with a score of <40 not to be SSc. With scores between 40 and 55 there was more diversity of opinion. Thus, it was concluded that the initial threshold would be a score of ≥56.

Reduction and testing of iterative changes. The 14 items in the scoring system were reduced to 9 while

Table 4. Sensitivity and specificity of the 2013 SSc classification criteria and previous SSc classification criteria, overall and in early SSc*

	Derivation sample (n = 200)		Validation sample (n = 405)		Validation sample, disease duration ≤3 years (n = 100)	
	Sensitivity (95% CI)	Specificity (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)
1980 ACR SSc criteria	0.80 (0.72–0.87)	0.77 (0.68–0.84)	0.75 (0.70–0.80)	0.72 (0.64–0.79)	0.75 (0.70–0.80)	0.72 (0.63–0.79)
2001 LeRoy/Medsger SSc criteria	0.76 (0.68–0.84)	0.69 (0.68–0.84)	0.75 (0.70–0.80)	0.78 (0.70–0.85)	0.80 (0.69–0.88)	0.76 (0.53–0.92)
2013 ACR/EULAR SSc criteria	0.95 (0.90–0.98)	0.93 (0.86–0.97)	0.91 (0.87–0.94)	0.92 (0.86–0.96)	0.91 (0.83–0.96)	0.90 (0.70–0.99)

* SSc = systemic sclerosis; 95% CI = 95% confidence interval; ACR = American College of Rheumatology; EULAR = European League Against Rheumatism.

maintaining sensitivity and specificity in the derivation sample. The items deleted were finger flexion contractures, calcinosis, tendon or bursal friction rubs, renal crisis, and esophageal dilation. Puffy fingers and sclerodactyly were combined into one item, and pulmonary arterial hypertension and interstitial lung disease were also combined into one item, resulting in 7 items for the scoring system. In the derivation sample, with reduction of the 14 items to 7, the sensitivity and specificity were 0.93 and 0.94, respectively. Weights were simplified by dividing each weight by 5 and rounding to the nearest integer. The threshold for this simplified scoring system was determined to be 9. The resulting sensitivity and specificity were 0.97 and 0.88, respectively.

Weights were further adjusted to align the scoring system with the experts' opinions (SSc or not SSc) on each of the 38 difficult-to-classify cases. To improve the specificity of the classification criteria, an exclusionary criterion was added: patients with a diagnosis that better explains their manifestations should not be classified as having SSc. These revisions resulted in the correct classification of all patient profiles judged to have SSc by the majority of experts.

The SSc classification criteria. The new classification criteria are presented in Table 1. The table shows the 1 criterion that, if present, is sufficient for classification as SSc, the 2 exclusionary criteria, and the 7 items with a combined threshold above which cases are classified as SSc. The classification criteria may be applied to patients who may have SSc and are being considered for inclusion in an SSc study. As noted above, they are *not to be applied* to patients who have a scleroderma-like disorder that better explains their manifestations; and patients with "*skin thickening sparing the fingers*" are not classified as having SSc.

If a patient has skin thickening of the fingers of both hands that extends proximal to the metacarpophalangeal joints, the classification system assigns 9 points for this one item alone, which is sufficient to classify the patient as having SSc with no further application of the point system needed. Otherwise, the point system is applied by adding the scores for manifestations that are "positive." The items are skin thickening of the fingers, fingertip lesions, telangiectasia, abnormal nailfold capillaries, pulmonary arterial hypertension and/or interstitial lung disease, Raynaud's phenomenon, and SSc-related autoantibodies. Two items, skin thickening of the fingers and fingertip lesions, include 2 different possible manifestations. If a patient has both manifestations, the score for the category is the higher score of the 2 manifestations. For example, in the item skin thickening of the fingers, if a patient has both manifestations, i.e., puffy fingers (weighted 2) and sclerodactyly (weighted 4), the total score for the item would be 4. The maximum possible score is 19, and patients with a score of ≥9 are classified as having SSc. The definitions of the items used in the criteria are provided in Table 2.

Validation. Table 3 shows the characteristics of the validation sample (268 patients with SSc, 137 controls). The sensitivity and specificity of the new SSc classification criteria were compared with those of the 1980 ACR classification criteria and the classification criteria proposed by LeRoy and Medsger, and the results are shown in Table 4. The sensitivity and specificity of the new SSc criteria were, respectively, 0.91 and 0.92 in the validation sample. The new criteria performed better than the 2 earlier classification schemes in terms of sensitivity and specificity ($P = 0.01$ versus the 1980 ACR criteria, $P = 0.004$ versus the LeRoy/Medsger criteria). The area under the receiver operating characteristic curve of the classification system tested against presence of SSc in the validation sample was 0.81 (95% confidence interval 0.77–0.85). The performance of the new criteria in patients with disease of ≤3 years' duration

* Profiles of 38 cases with likely systemic sclerosis (SSc) or an SSc-like disorder, with presence or absence of the manifestations in the newly developed American College of Rheumatology (ACR)/European League Against Rheumatism SSc classification criteria, are shown. The cases are listed in order of the points awarded using the classification system (Score column) and are classified as SSc if the score is ≥9. For 18 of the cases, the number of experts agreeing that the case had SSc is shown. None of the cases had skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints (the single criteria that, if present, immediately classifies the individual as having SSc). Whole finger is sclerodactyly of the entire finger but not proximal to the metacarpophalangeal joints. ILD = interstitial lung disease; PAH = pulmonary arterial hypertension; ? = inconclusive; NA = not applicable (experts were not asked); PIP = proximal interphalangeal.

was similar to the performance in the group overall (Table 4).

The classification system was additionally tested against expert opinion (n = 16 experts), using the set of 38 selected cases (Table 5). All of the cases scoring ≥9 were considered SSc, whereas cases scoring <9 were regarded as not being SSc or were controversial. With the proposed system all of these cases were classified in accordance with consensus-based expert opinion. All cases that were classified as SSc with the 1980 ACR criteria were also classified as SSc with the new criteria, as were several cases not classified as SSc with the 1980 ACR criteria.

Discussion

A classification system for systemic sclerosis is needed to ensure that all patients categorized as having SSc for inclusion in studies do indeed have the disease, based on specific defined characteristics. The major reason to revise the 1980 ACR criteria was that those criteria lacked adequate sensitivity, especially in patients with early SSc or with limited cutaneous SSc (9,10,18). The proposed classification criteria are superior and exhibit greater sensitivity and specificity compared to the 1980 criteria and the classification criteria proposed

by LeRoy and Medsger. All profiles of patients who were considered to have SSc by a majority of experts were indeed classified as SSc with the new classification system, and the new system is more inclusive and also performs well in patients with early disease (≤3 years since diagnosis).

The newly developed classification system includes disease manifestations of the 3 hallmarks of SSc: fibrosis of the skin and/or internal organs, production of certain autoantibodies, and vasculopathy. The 4 items comprising the 1980 ACR classification criteria (scleroderma proximal to the metacarpophalangeal joints, sclerodactyly, digital pitting scars [not pulp loss], and bilateral basilar pulmonary fibrosis) (3) are also included, as are the items in the criteria proposed in 2001 by LeRoy and Medsger (Raynaud's phenomenon, autoantibodies, nailfold capillaroscopy abnormalities, skin fibrosis) (6).

The new criteria include 1 criterion that alone is sufficient for classification as SSc: skin thickening of the fingers extending proximal to the metacarpophalangeal joints, which is similar to the 1980 criteria. If the single sufficient criterion is not fulfilled, the point system is applied and patients with a score of ≥9 are classified as having SSc. All items in the classification criteria represent measurements that are performed in routine clinical practice. The criteria are meant for inclusion of SSc patients in studies, not for SSc diagnosis. Although the list of items in the classification criteria mimics the list of items one usually uses for diagnosis, in practice the diagnosis of SSc may also be informed by items not included in the classification criteria, such as tendon friction rubs, calcinosis, and dysphagia. Consequently, patients *classified* as having SSc are a subset of patients being *diagnosed* as having SSc, with diagnosis being more sensitive. Ideally, there would be no difference between diagnosis and classification criteria.

As intended, the new classification system incorporates the considerable advances made in the diagnosis of SSc. It includes the concept of specific serum autoantibodies such as anti–topoisomerase I, anticentromere, and anti–RNA polymerase III (15,23). There is the possibility that testing for additional SSc autoantibodies, such as anti-Th/To, anti–U3 RNP, and others, may become more widely available. The criteria also acknowledge the value of magnified nailfold visualization in the diagnosis of SSc (14,15). Although capillaroscopy can be performed with highly specialized equipment such as videocapillaroscopy cameras, simple in-office ophthalmoscopes or dermatoscopes suffice for distinguishing between normal and abnormal nailfold capillaries (24,25). Capillaroscopy is now widely used, and considering the value of magnified nailfold visualization in the diagnosis and management of SSc, these new criteria may encourage acquisition of this skill by physicians caring for SSc patients. Likewise, criteria for pulmonary artery hypertension have changed over the years. The ACR/EULAR committee recognizes this, and the diagnosis of pulmonary artery hypertension should be based on the most recent accepted criteria from right-sided heart catheterization.

Several items that are useful for recognizing SSc in clinical practice, such as calcinosis, flexion contractures of the fingers, tendon or bursal friction rubs, renal crisis, esophageal dilatation, and dysphagia are not included in the criteria. These were considered but did not substantially improve sensitivity or specificity. For example, renal crisis is a strong indicator of SSc, but its low frequency of occurrence makes it less useful for the purpose of classification (20). The committee considered a non–point-based additive system (8), such as the ACR systemic lupus erythematosus criteria (26) or the 1980 ACR SSc criteria. We concluded, however, that assigning weights yielded superior results for SSc classification. Indeed, the weights were simplified to single-digit numbers to make the system easy to use even in the absence of a computing device. Similar weighted systems have been used for other rheumatic diseases (27). The committee also decided not to include "probable" or "possible" SSc in the classification.

Examples of profiles not captured by the 1980 ACR criteria that fulfilled the new classification criteria are combinations of skin thickening of the whole finger, SSc-related autoantibodies, and pulmonary arterial hypertension and/or Raynaud's phenomenon. A patient with Raynaud's phenomenon, autoantibodies, and abnormal nailfold capillaries is not classified as having SSc, although such a patient may develop SSc over subsequent years (6,15).

Patients may have disease manifestations similar to those of SSc that are better explained by another well-defined disorder, such as nephrogenic sclerosing fibrosis, generalized morphea, eosinophilic fasciitis, scleredema diabeticorum, scleromyxedema, porphyria, lichen sclerosis, graft-versus-host disease, or diabetic cheiroarthropathy. We decided it was not necessary to develop criteria that differentiated SSc specifically from these conditions. Patients with some of these diseases were included in the validation cohort of patients with SSc-like disorders, and it is possible that specificity may have been slightly higher had they been excluded.

In developing the revised SSc classification crite-

ria, we followed the recommendations and guidelines of the ACR and EULAR, which included 1) collaboration between clinical experts and clinical epidemiologists in criteria development, 2) evaluation of the psychometric properties of each candidate criterion, and 3) description of the test sample (origin of the patients and control subjects) (7,28). Ideally, phases of criteria development should have a balance between expert opinion and data-driven methods; yet, there should be avoidance of circularity of reasoning (a bias that can occur when the same experts developing the criteria are the ones contributing cases and comparison patients) (29). We included different experts at different steps in the development of the SSc criteria, to avoid circularity.

Testing and validating a classification system for SSc is difficult because there is no gold standard for defining a particular case as SSc; that is, there is no incontrovertible test or criterion. We relied on expert opinion for our gold standard, which is similar to the process used in the development of other criteria (8).

In the absence of a gold standard, we developed and tested the proposed classification system against two standards of expert opinion: 1) the opinion of the clinician who selected cases for the North American and European derivation and validation cohorts, and 2) the combined opinion of a group of clinical experts in SSc. Both standards have strengths and weaknesses. Each individual clinician who selected cases had access to information that could have included aspects not captured by the forms, which were restricted to 23 particular manifestations. Data were obtained from several sites in Europe and North America, so this should improve generalizability and reduce selection bias. However, it is possible that other expert clinicians may have had a different opinion about particular cases. The consensus opinion of a group of experts who had the opportunity to discuss controversial cases strengthens the combined expert opinion. However, the group may not have been aware of some relevant information not included in the available data. It is also difficult for a group of experts to consider hundreds of cases in depth; however, this was managed by having the group consider in depth only those cases, or combinations of items, that appeared to be controversial. In this way, the expert group was able to form a consensus over the whole range of cases in the database. A key strength of the present work is the use of both standards for testing and validation of the proposed system.

The approach we used has other strengths and limitations as well. The methodology was state of the art, with validation by data and by expert opinion at every step. Various methods used in the development process have already been described (19,20). The criteria have face validity, because the items are routinely assessed in daily clinical practice and also were included in other important SSc classification criteria sets. The criteria allow for new developments in e.g., autoantibody testing availability and/or new identification of scleroderma-associated autoantibodies, or assessment of nailfold capillaries. Formal conjoint analysis to derive the weights associated with items improved the sensitivity and specificity of the items, as was found also in the development of the recent ACR/EULAR criteria for the classification of rheumatoid arthritis (30).

The criteria have not been validated in ethnic groups that are not common in North America and Europe. This will require further studies. Regarding clinical use, the number of items and weights may not be easy to remember, but wide availability and (electronic) applications can be developed. The SSc classification criteria steering committee and the expert consultants agreed that the criteria could allow for classification of patients with another rheumatic disease as also having SSc (e.g., having both systemic lupus erythematosus and SSc, or rheumatoid arthritis and SSc, etc.). Although this is a possible limitation, it permits individual researchers to decide whether to include subjects who fulfill criteria for more than one rheumatic disease in any particular study.

Conclusions

The ACR/EULAR classification criteria for SSc perform better than 1980 ACR preliminary criteria in terms of both sensitivity and specificity. They are relatively simple to apply to individual subjects. These criteria may be endorsed as inclusion criteria for SSc studies. Validation in other populations is encouraged.

Abstract. **Therapy for polymyalgia rheumatica (PMR) varies widely in clinical practice as international recommendations for PMR treatment are not currently available. In this paper, we report the 2015 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) recommendations for the management of PMR. We used the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) methodology as a framework for the project. Accordingly, the direction and strength of the recommendations are based on the quality of evidence, the balance between desirable and undesirable effects, patients' and clinicians' values and preferences, and resource use. Eight overarching principles and nine specific recommendations were developed covering several aspects of PMR, including basic and follow-up investigations of patients under treatment, risk factor assessment, medical access for patients and specialist referral, treatment strategies such as initial glucocorticoid (GC) doses and subsequent tapering regimens, use of intramuscular GCs and disease modifying anti-rheumatic drugs (DMARDs), as well as the roles of non-steroidal anti-rheumatic drugs and non-pharmacological interventions. These recommendations will inform primary, secondary and tertiary care physicians about an international consensus on the management of PMR. These recommendations should serve to inform clinicians about best practices in the care of patients with PMR.**

Introduction

There are wide variations in the treatment of polymyalgia rheumatica (PMR) with respect to glucocorticoid (GC) dosages, tapering strategies, use of disease modifying anti-rheumatic drugs (DMARDs) and duration of treatment. Up to 29–45% of patients with PMR do not adequately respond to GCs within 3–4 weeks. Relapses and long-term GC dependency are common (1–4). GC side effects are frequently observed, occurring in around 50% of patients, and present a further challenge (5,6). Well considered, international recommendations can serve to standardize practice and improve patient care.

Primary objective of the recommendations. These recommendations are intended for the management of patients with PMR in various settings and are based on clinical evidence and expert opinion including informed patient decision-making.

Target population. The target population are patients with PMR based on clinician diagnosis which may be supported by currently available diagnostic or classification criteria (3,4,7–11). Management of PMR with concomitant giant cell arteritis (GCA), rheumatoid arthritis (RA) or other conditions that present with PMR features or mimic PMR is not addressed by these recommendations.

Target users. The target users of these recommendations are primary, secondary and tertiary care physicians (that is, general practitioners [GPs], specialists in general [internal] medicine and rheumatologists).

Methods

For a detailed description of methods, see online supplementary file S1, on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract.

In brief, we used the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) methodology as a framework (12–15). We formulated 12 PICO (problem/population, intervention, comparison, and outcome) questions on interventions and 10 questions on prognostic factors (see online supplementary box S1A and S1B [http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract], or the accompanying paper by Dejaco et al [16]). The systematic literature review (SLR) was conducted by two investigators (CDe and YPS) using Ovid MEDLINE, Embase, PubMed, CINAHL, Web of Science and the Cochrane Library databases (from January 1970 until April 2014), and applying the thesauri of PMR, text words, abbreviations and truncated text words. Outcome parameters used in the SLR may be found in supplementary box S2 (http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract). Quality appraisal of interventional and prognostic studies was performed using GRADE (17,18) and the Quality in Prognostic Studies (QUIPS) tool (19), respectively. According to GRADE methodology, a guideline panel should consider the following aspects when formulating recommendations: 1) overall quality of evidence; 2) balance between desirable and undesirable effects; 3) patients' and clinicians' values and preferences; and 4) resource use. External evidence (from other American College of Rheumatology [ACR]/European League Against Rheumatism [EULAR] recommendations; see online supplementary table S1 [http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract] for details) on safety aspects related to the use of nonsteroidal anti-inflammatory drugs (NSAIDs), GCs and methotrexate (MTX) was taken into account as indirect evidence, in order to identify the optimal trade-off between the benefit and harm of interventions. Prognostic factors were used to build subgroups and to adapt the recommendations based on the presence or absence of unfavorable prognostic factors. Final recommendations were either "in favor" or "against" an intervention, and were graded as "conditional" or "strong." A strong recommendation in favor (against) was considered when the panel was certain that benefits did (did not) outweigh risks and burdens, the preferences/values of patients were met (not met) and resource use was reasonable (unreasonably high). If uncertainty existed, a conditional recommendation was made.

Results

The results of the SLR are reported in a separate manuscript (16). See online supplementary file S2 (on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract) for a summary of the SLR and external evidence considered by the guideline panel.

General aspects. These recommendations should be understood as clinical advice and do not dictate the care of a particular patient. The EULAR and ACR consider adherence to these recommendations to be voluntary, with the physician making the ultimate decision to apply them in light of each patient's individual circumstances.

Overarching principles for the management of PMR. The group agreed upon several principles deemed to be fundamental aspects of clinical care in PMR as detailed in Box 1. These principles have not directly resulted from the SLR, but are consensus based. They are intended as a framework for the implementation of

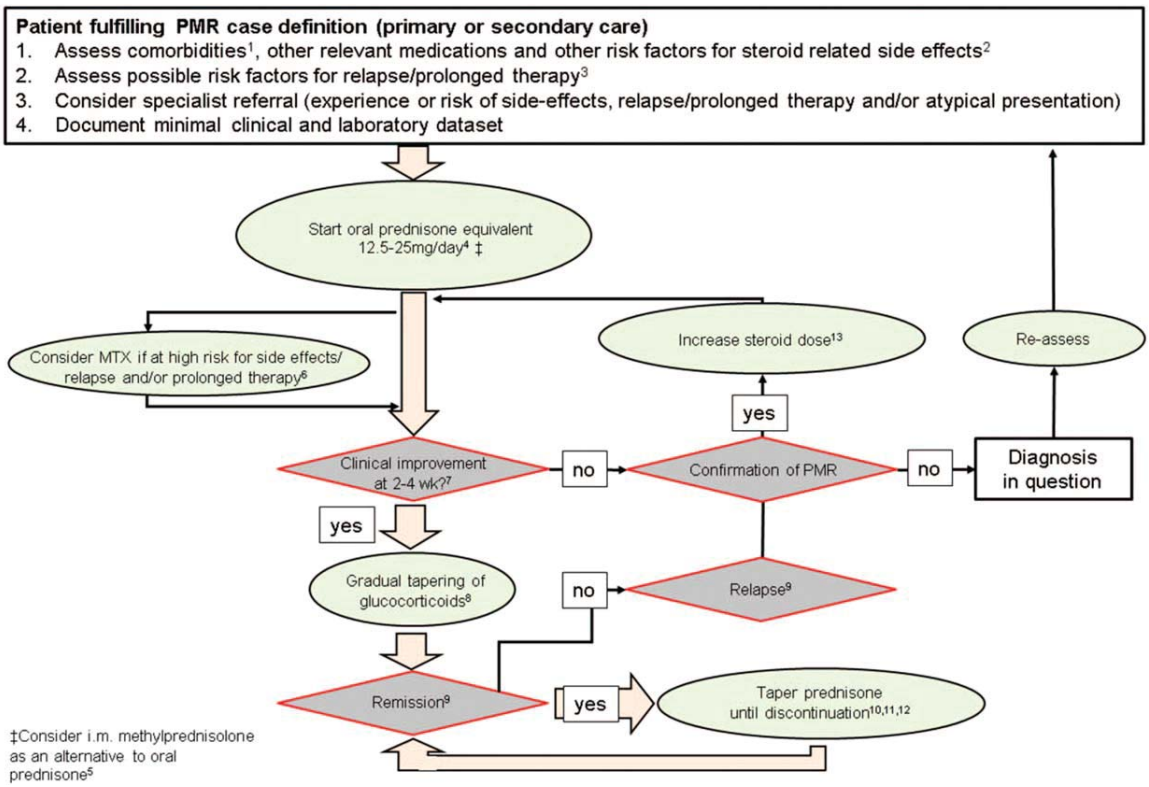
Box 1. Summary of the 2015 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) recommendations for the management of polymyalgia rheumatica (PMR)

Target population:
Patients with PMR based on clinician diagnosis which may be supported by currently available diagnostic or classification criteria (3,4,7–11).
Overarching principles for the management of PMR:

A. Adoption of a safe and specific approach to ascertain the PMR case definition. The clinical evaluation should be directed toward exclusion of relevant mimicking (eg, non-inflammatory, inflammatory (such as giant cell arteritis or rheumatoid arthritis), drug-induced, endocrine, infective and neoplastic) conditions.
B. Every case of PMR should have the following assessments prior to the prescription of therapy (primary or secondary care):
   - ▶ Documentation of a basic laboratory dataset. This will help to exclude mimicking conditions and establish a baseline for monitoring of therapy. This should include rheumatoid factor and/or anti–cyclic citrullinated peptide antibodies (ACPA), C-reactive protein and/or erythrocyte sedimentation rate (ESR), blood count, glucose, creatinine, liver function tests, bone profile (including calcium, alkaline phosphatase) and dipstick urinalysis. Additional investigations to consider are protein electrophoresis, thyroid stimulating hormone (TSH), creatine kinase and vitamin D.
   - ▶ Depending on clinical signs and symptoms and the likelihood of the alternative diagnoses, additional more extensive serological tests such as anti-nuclear antibodies (ANA), anti–cytoplasmic neutrophil antibodies (ANCA) or tuberculosis tests may be performed to exclude mimicking conditions. Additional investigations such as chest radiographs may be considered at the discretion of the physician in order to exclude other diagnoses.
   - ▶ Determination of comorbidities (particularly hypertension, diabetes, glucose intolerance, cardiovascular disease, dyslipidemia, peptic ulcer, osteoporosis [and particularly recent fractures]), presence of cataract or (risk factors for) glaucoma, presence of chronic or recurrent infections, and co-medication with non-steroidal anti-inflammatory drugs (NSAIDs) as outlined in Smolen et al (21) and Gossec et al (22), other relevant medications and risk factors for steroid-related side effects. Female sex was associated with a higher risk of glucocorticoid (GC) side effects in low to moderate quality studies (23–25).
   - ▶ The role of risk factors for relapse/prolonged therapy is not clear yet. Baseline factors that were associated in low to moderate quality studies with a higher relapse rate and/or prolonged therapy in PMR studies were: female sex (24,26), high ESR (>40 mm/hour) (26–31) and peripheral inflammatory arthritis (32). A number of equally low to moderate quality studies, however, failed to demonstrate an association between these factors and relapse/prolonged therapy (27–30,32–44).
C. Consideration of specialist referral, particularly in case of atypical presentation (such as peripheral inflammatory arthritis, systemic symptoms, low inflammatory markers, age <60 years), experience of or high risk of therapy-related side effects, PMR refractory to GC therapy, and/or relapses/prolonged therapy.
D. Treatment of PMR patients should aim at the best care and must be based on a shared decision between the patient and the treating physician.
E. Patients should have an individualized PMR management plan. Patient perspective and preferences should be considered in the individualized choice of initial GC dose and subsequent tapering of GCs in PMR.
F. Patients should have access to education focusing on the impact of PMR and treatment (including comorbidities and disease predictors) and advice on individually tailored exercise programs.
G. Every patient treated for PMR in primary or secondary care should be monitored with the following assessments: risk factors and evidence for steroid-related side effects, comorbidities, other relevant medications, evidence and risk factors for relapse/prolonged therapy. Continuous documentation of a minimal clinical and laboratory dataset should be conducted while prescribing GCs. Follow-up visits are suggested every 4–8 weeks in the first year, every 8–12 weeks in the second year, and as indicated in case of relapse or as prednisone is tapered and discontinued.
H. It is important for patients to have rapid and direct access to advice from doctors, nurses or trained allied healthcare staff to report any changes in their condition such as flares and adverse events.

Specific recommendations for the management of PMR patients:

1. The panel strongly recommends using GC instead of NSAIDs in patients with PMR, with the exception of possible short-term use of NSAIDs and/or analgesics in PMR patients with pain related to other conditions. No specific recommendation can be made for analgesics.
2. The panel strongly recommends using the minimum effective individualized duration of GC therapy in PMR patients.
3. The panel conditionally recommends using the minimum effective GC dose within a range of 12.5–25 mg prednisone equivalent daily as the initial treatment of PMR. A higher initial prednisone dose within this range may be considered in patients with a high risk of relapse and low risk of adverse events, whereas in patients with relevant comorbidities (eg, diabetes, osteoporosis, glaucoma, etc.) and other risk factors for GC-related side effects, a lower dose may be preferred. The panel discourages conditionally the use of initial doses ≤7.5 mg/day and strongly recommends against the use of initial doses >30 mg/day.
4. The panel strongly recommends individualizing dose tapering schedules, predicated to regular monitoring of patient disease activity, laboratory markers and adverse events.The following principles of GC dose tapering are suggested:
   A. Initial tapering: Taper dose to an oral dose of 10 mg/day prednisone equivalent within 4–8 weeks.
   B. Relapse therapy: Increase oral prednisone to the pre-relapse dose and decrease it gradually (within 4–8 weeks) to the dose at which the relapse occurred.
   C. Tapering once remission is achieved (following initial and relapse therapies): Taper daily oral prednisone by 1 mg every 4 weeks (or by 1.25 mg decrements using schedules such as 10/7.5 mg alternate days, etc.) until discontinuation given that remission is maintained.
5. The panel conditionally recommends considering intramuscular (i.m.) methylprednisolone as an alternative to oral GCs. The choice between oral GCs and i.m. methylprednisolone remains at the discretion of the treating physician. In one clinical trial, a starting dose of 120 mg methylprednisolone i.m. injection every 3 weeks was applied (23).
6. The panel conditionally recommends using a single rather than divided daily doses of oral GCs for the treatment of PMR, except for special situations such as prominent night pain while tapering GCs below the low-dose range (prednisone or equivalent <5 mg daily).
7. The panel conditionally recommends considering early introduction of methotrexate (MTX) in addition to GCs, particularly in patients at a high risk for relapse and/or prolonged therapy as well as in cases with risk factors, comorbidities and/or concomitant medications where GC-related adverse events are more likely to occur. MTX may also be considered during follow-up of patients with a relapse, without significant response to GC or experiencing GC-related adverse events. MTX has been used at oral doses of 7.5–10 mg/week in clinical trials (24–27).
8. The panel strongly recommends against the use of TNFα blocking agents for treatment of PMR.
9. The panel conditionally recommends considering an individualized exercise program for PMR patients aimed at the maintenance of muscle mass and function, and reducing risk of falls especially in older persons on long-term GCs as well as in frail patients.
10. The panel strongly recommends against the use of the Chinese herbal preparations Yanghe and Biqi capsules in PMR patients.



Patient fulfilling PMR case definition (primary or secondary care)
1. Assess comorbidities[1], other relevant medications and other risk factors for steroid related side effects[2]
2. Assess possible risk factors for relapse/prolonged therapy[3]
3. Consider specialist referral (experience or risk of side-effects, relapse/prolonged therapy and/or atypical presentation)
4. Document minimal clinical and laboratory dataset
Start oral prednisone equivalent 12.5-25mg/day[4] ‡
Consider MTX if at high risk for side effects/ relapse and/or prolonged therapy[6]
Increase steroid dose[13]
Re-assess
yes
Clinical improvement at 2-4 wk?[7]
no
Confirmation of PMR
no
Diagnosis in question
yes
Gradual tapering of glucocorticoids[8]
no
Relapse[9]
Remission[9]
yes
Taper prednisone until discontinuation[10,11,12]
‡Consider i.m. methylprednisolone as an alternative to oral prednisone[5]

Figure 1. Algorithm based on the 2015 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) recommendations for the management of polymyalgia rheumatica (PMR). The algorithm is applied to patients with PMR based on clinician diagnosis which may be supported by currently available diagnostic or classification criteria (3,4,7–11). The algorithm assumes the consideration of overarching principles emphasizing the importance of assessing comorbidities, other relevant medications and possible risk factors for steroid-related side effects and relapse/prolonged therapy. In addition, patients diagnosed in primary care should be considered for specialist referral, particularly in case of atypical presentation (such as peripheral inflammatory arthritis, systemic symptoms, low inflammatory markers, age <60 years), experience or high risk of therapy-related side effects and/or relapse/prolonged therapy. A minimal clinical and laboratory dataset should be documented in each patient before prescribing therapy. [1]Examples for comorbidities associated with an increased risk of glucocorticoid (GC)–related side effects are (according to Duru et al [32] and Hoes et al [35]): hypertension, diabetes, glucose intolerance, cardiovascular disease, dyslipidemia, peptic ulcer, osteoporosis (and particularly recent fractures), presence of cataract or (risk factors for) glaucoma, presence of chronic or recurrent infections, and co-medication with NSAIDs. [2]A baseline factor that was associated with a higher risk of GC-related adverse events in PMR studies was: female sex (37–39). [3]The role of risk factors for relapse/prolonged therapy is not yet clear. Baseline factors that were associated with a higher relapse rate and/or prolonged therapy in PMR studies were: female sex (38,47), high erythrocyte sedimentation rate (ESR) (>40 mm/hour) (47–51,53) and peripheral inflammatory arthritis (54). A number of studies, however, failed to demonstrate association between these factors and relapse (48–51,54,67–78). [4]Use the minimum effective dose out of a range of 12.5–25 mg prednisone equivalent daily: a high risk of relapse/prolonged therapy favors a higher dose, while a high risk of side effects favors a lower dose. [5]In one randomized controlled trial, 120 mg methylprednisolone intramuscular (i.m.) injection was used every 3 weeks as a starting dose (23). I.m. methylprednisolone may not be available in all countries and the possible long-term benefit in terms of efficacy and GC-sparing effects of this preparation is unknown. [6]Methotrexate (MTX) has been used at oral doses of 7.5–10 mg/week in clinical trials (24–27). [7]Clinical improvement should be noted after 2 weeks, and almost complete response can be expected after 4 weeks. The definition of response criteria was beyond the scope of this project; however, a definition of response was proposed in Dasgupta et al (3,4) [8]For initial GC tapering, we recommend reducing the oral dose gradually to a dose of 10 mg/day prednisone equivalent within 4–8 weeks; after relapse therapy the dose should be decreased gradually (within 4–8 weeks) to the dose at which the relapse occurred. For i.m. methylprednisolone, a dose of 120 mg every 3 weeks was used for the first 9 weeks in Dasgupta et al (23). No recommendation about dose adjustments of MTX can be made. [9]The definition of criteria for remission and relapse was beyond the scope of this project. Definitions of remission and relapse used in clinical studies are summarized in Dejaco et al (65). [10]Once remission is achieved (following initial and relapse therapies), taper oral prednisone by 1 mg/4 weeks (or similar, eg, 2.5 mg/10 weeks) until discontinuation given that remission is maintained. In case i.m. methylprednisolone is used, the following tapering regimen was previously applied (23): 100 mg methylprednisolone i.m. at week 12, then continuation of the injections at monthly intervals with the dose reduced by 20 mg every 12 weeks until week 48. Thereafter, the dose was reduced by 20 mg every 16 weeks until discontinuation. [11]The group suggests that PMR patients be followed up every 4–8 weeks in the first year, every 8–12 weeks in the second year and as indicated in case of relapse or as prednisone is tapered off. [12]No recommendation can be made for minimal/optimal duration of therapy. In case patients are treated with a combination of GCs plus MTX and GCs have been withdrawn already, discontinuation of MTX may be considered. [13]Initial lack of response (eg, insufficient improvement of symptoms within 2 weeks): increase oral dose up to 25 mg prednisone equivalent. In case i.m. methylprednisolone is used, consider switching to oral GCs. Relapse therapy: increase dose to the previously effective (ie, pre-relapse) dose.

the specific treatment recommendations and are of a general "overarching" nature, a concept adapted from earlier EULAR recommendations (20–22).

Specific recommendations. See Box 1 for a summary of the recommendations. A flow-chart for the management of PMR patients is depicted in Figure 1.

Recommendation 1: (PICO 1) The panel strongly recommends using GCs instead of NSAIDs in patients with PMR, with the exception of possible short-term use of NSAIDs and/or analgesics in PMR patients with pain related to other conditions (eg, co-existing osteoarthritis). No specific recommendation can be made for analgesics.

Explanation: The group recommends strongly against the use of NSAIDs compared to GCs in the treatment of PMR since the relative harm of long-term NSAID use (as mainly indicated by external evidence) outweighs the possible small benefits in PMR. No specific recommendation can be made for analgesics. On a basis of consensus, the panel recognized that the short-term use of NSAIDs and/or analgesics may be necessary in the setting of pain related to conditions other than PMR.

Recommendation 2: (PICO 2) The panel strongly recommends using the minimum effective individualized duration of GC therapy in PMR patients.

A more specific recommendation is not possible due to the lack of published evidence on this issue. On a basis of consensus and in accordance with the overarching principles, the group unanimously agreed to choose the minimum effective individualized duration and dose of GCs to balance benefit versus harm after assessing risk factors for GC-related adverse events, comorbidities, concomitant medications, relapses and prolonged therapy. Our recommended GC tapering schedule (see Recommendation 4) assumes a minimum of 12 months of treatment. A more specific statement is not possible because of the lack of PMR studies on this particular topic and because of the multiple subgroups and factors that need to be taken into account.

Recommendation 3: (PICOs 3–5) The panel conditionally recommends using the minimum effective GC dose within a range of 12.5–25 mg prednisone equivalent daily as the initial treatment of PMR. A higher initial prednisone dose within this range may be considered in patients with a high risk of relapse and low risk of adverse events, whereas in patients with relevant comorbidities (eg, diabetes, osteoporosis, glaucoma, etc.) and other risk factors for GC-related side effects, a lower dose may be preferred. The panel discourages conditionally the use of initial doses $\leq$7.5 mg/day and strongly recommends against the use of initial doses $>$30 mg/day.

According to the SLR on prognostic factors and based on clinical experience, the group agreed upon the existence of various PMR subgroups that are characterized by different risks of relapse, prolonged GC therapy and/or GC-related adverse events as well as by various comorbidities and co-medications. As there are insufficient data to make evidence-based recommendations for all conceivable subgroups, and taking current clinical practice into account (28–30), the panel agreed upon the use of the minimum effective GC dose out of a range of 12.5–25 mg prednisone equivalent daily balancing benefits versus harms. The panel did not construct case vignettes as a possible aid for clinical practice; however, it is suggested that a higher initial prednisone dose (within the given range) may be used in patients with a high risk of relapse and low risk of adverse events, whereas in patients with relevant comorbidities (eg, diabetes, osteoporosis, glaucoma, etc.) and other risk factors for GC-related side effects, a lower dose may be preferred.

The group conditionally discourages low ($\leq$7.5 mg/day) and strongly recommends against high ($>$30 mg/day prednisone equivalent) initial GC doses. For this statement the group extrapolated the data from randomized controlled trials (29,31), and took clinical experience, national PMR guidelines (28–30), as well as current ACR and/or EULAR recommendations on the use of GCs in rheumatic diseases into account (32–35). In addition, there is incontrovertible external evidence of harm from long-term large doses of GCs (32–35) and lack of evidence for any benefit of a high-dose regimen in PMR. It was unanimously agreed among the group that patients requiring high doses of GCs should be evaluated for alternate diagnoses and an alternate management plan.

Recommendation 4: (PICO 6) The panel strongly recommends individualizing dose-tapering schedules, based on regular monitoring of patient disease activity, laboratory markers and adverse events.

The following principles of GC dose tapering are suggested:

A. Initial tapering: Taper dose to an oral dose of 10 mg/day prednisone equivalent within 4–8 weeks.
B. Relapse therapy: Increase oral prednisone to the pre-relapse dose and decrease it gradually (within 4–8 weeks) to the dose at which the relapse occurred.
C. Tapering once remission is achieved (following initial and relapse therapies): Taper daily oral prednisone by 1 mg every 4 weeks (or by 1.25 mg decrements using schedules such as 10/7.5 mg on alternate days, etc.) until discontinuation as long as remission is maintained.

In accordance with the overarching principles, the panel agreed upon a strong recommendation to

individualize dose tapering and to regularly monitor PMR patients. Further, the panel proposed general principles for initial and post-relapse tapering of GCs (based on consensus and current clinical practice) but did not fix a schedule as in other guidelines (28–30). The panel agreed that equivalent objectives may be achieved by alternative tapering schedules. For example, a patient with a high initial prednisone dose (eg, 25 mg/day) may have a fast initial taper followed by a more gradual decrease in the GC dose, whereas in a patient starting at a lower initial dose (eg, 12.5 mg/day), the initial dose may be kept constant for longer and then eventually reduced.

The group suggested prednisone should be tapered by 1 mg/4 weeks or similar once remission is achieved. Again, the panel emphasized the important overall principle of gradual GC reduction without the need to prescribe a fixed schedule. The group further recognized that 1 mg prednisone tablets are not available in all countries (making a reduction of 1 mg/4 weeks unfeasible) and that other regimens such as alternate day reductions (eg, 10/7.5 mg on alternate days, etc.) are common clinical practice (28).

Recommendation 5: (PICO 7) The panel conditionally recommends considering intramuscular (i.m.) methylprednisolone as an alternative to oral GCs. The choice between oral GCs and i.m. methylprednisolone remains at the discretion of the treating physician.

In one clinical trial, i.m. methylprednisolone was applied at a dose of 120 mg every 3 weeks until week 9. At week 12, 100 mg were used and subsequently, injections were continued at monthly intervals and the dose was reduced by 20 mg every 12 weeks until week 48. Thereafter, the dose was reduced by 20 mg every 16 weeks until discontinuation (23,36).

The panel did not specify a clinical phenotype where i.m. GCs would be appropriate or adequate therapy; however, the panel agreed that in clinical practice this preparation may be considered in cases where a lower cumulative GC dose is desirable, for example in female patients with difficult to control hypertension, diabetes, osteoporosis and/or glaucoma (37–39). Nonetheless, the panel acknowledged that there is a lack of convincing evidence showing significantly fewer side effects with i.m. methylprednisolone than with oral GC therapy.

The reasons why the panel did not endorse a strong recommendation for the use of i.m. methylprednisolone are the following: 1) the efficacy of i.m. methylprednisolone is supported by a single randomized controlled trial and confirmation of these data is still necessary (23,36); 2) this trial was neither designed nor powered as a non-inferiority trial and therefore, a difference between the efficacy of i.m. and oral GC cannot be excluded; 3) the trial failed to demonstrate a reduction in GC-related adverse events except for weight gain; 4) the long-term benefit of this preparation is unknown (particularly with respect to a possible reduction in GC side effects); and 5) i.m. methylprednisolone is not available in all countries.

Recommendation 6: (PICO 8) The panel conditionally recommends using a single rather than divided daily doses of oral GCs for the treatment of PMR, except for special situations such as prominent night pain while tapering GCs below the low-dose range (prednisone or equivalent <5 mg daily).

There are no studies available addressing this issue specifically in PMR. Based on clinical experience and because of the concern that adverse events (including disturbance of the hypothalamic–pituitary–adrenal axis) may be higher with divided doses, the group agreed against the general use of divided GC doses in PMR (40–43). The effectiveness and acceptability of a single daily GC dose has been standard clinical practice in PMR and other inflammatory conditions (44,45) and evening doses can cause circadian rhythm and sleep disturbances (46).

In special situations such as in case of night pain while tapering below the low-dose range (prednisone or equivalent <5 mg daily), split doses may be considered. However, persistent breakthrough symptoms should prompt re-consideration of the diagnosis.

Recommendation 7: (PICO 9) The panel conditionally recommends considering early introduction of MTX in addition to GCs, particularly in patients at high risk of relapse and/or prolonged therapy as well as in cases with risk factors, comorbidities and/or concomitant medications where GC-related adverse events are more likely to occur. MTX may also be considered during follow-up in patients with a relapse, without a significant response to GC or experiencing GC-related adverse events.

In clinical trials, MTX has been used at oral doses of 7.5–10 mg/week (24–27).

Similar to the explanation of Recommendation 5, the panel felt that there is no clinical prototype unconditionally warranting treatment with MTX, rather the use of this drug should be discussed on an individual basis. In clinical practice, MTX may be considered for example in female patients (36,39,47) with high initial erythrocyte sedimentation rate (ESR) (>40 mm/hour) (48–53), peripheral inflammatory arthritis (54) and/or comorbidities that may be exacerbated by GC therapy.

The panel also reached a consensus that MTX should be considered in patients who have relapsed (either on or off GCs), cases without significant response

Box 2. Research agenda

The group agreed that future studies in polymyalgia rheumatica (PMR) should be multicenter and properly powered using an agreed, validated core outcome set and a robust trial design that would maximize the power of studies, facilitate regulatory approvals and allow future meta-analysis.

Specific research questions:

1. Which outcome measures including patient-related outcomes, and response, remission and relapse criteria should be used in PMR? What is the value of a composite score? What are the most relevant treatment targets in PMR?
2. **What is the efficacy and safety of different routes of glucocorticoid (GC) administration (oral, intramuscular, intra-articular), different initial GC doses, various GC tapering regimens, and different GC flare doses?**
3. **What is the efficacy and safety of DMARDs (non-TNFα biologic, conventional synthetic and conventional targeted) in PMR? What is the optimal strategy for using DMARDs in PMR: monotherapy versus combination therapy, early versus late introduction, and (particularly for biologics) use with or without GCs?**
4. What is the minimal/optimal duration of therapy and which strategies for withdrawing GCs and/or DMARDs yield the best efficacy/safety profile?
5. **What is the optimal strategy for shared primary and specialty care including recommendations for specialist referral? How can patients be better involved in treatment decisions, and are there any decision aids? What is the role of self-management?**
6. What is the value of tight control (ie, treat to target) versus conventional management strategies in PMR?
7. **How should patients with long-standing disease and long-term low-dose GC therapy be managed?**
8. What is the cost utility and effectiveness of DMARD use in PMR (versus GC use alone)?
9. What is the value of non-pharmacological therapies in PMR? Particularly, it is assumed but not yet demonstrated that physiotherapy may support preservation of function and reduce the risk of adverse events related to GC use. Patients may benefit from exercise by maintaining muscle mass and function as well as by fall prevention especially in the frail. What is the role of diet in PMR and nutrition supplements (eg, fish oil) related to outcomes?
10. What is the efficacy and safety of herbal preparations in PMR?
11. What is the role of imaging (particularly ultrasound) for the assessment and monitoring of PMR, identification of overlap with other diseases (eg, large vessel vasculitis or inflammatory arthritis) alongside clinical and patient reported outcomes?
12. **Which biomarkers may be useful in PMR? Why do some patients do better than others? How can we identify these groups and what is the biological mechanism behind it? Should different drugs be applied to different PMR subgroups?**
13. What is the morbidity and mortality of PMR patients (with a particular focus on cardiovascular risk) in long-term observational studies?
14. What is the etiopathogenesis of PMR? Which targeted therapies could be developed based on new knowledge of disease mechanisms?

Bolded points indicate the top 5 items of the research agenda according to the opinion of the guideline panel.

to GC or patients experiencing GC-related adverse events. The group further agreed that MTX may be used with oral or i.m. GC preparations even if the concomitant use of MTX and i.m. methylprednisolone has not been tested formally.

The efficacy of MTX was addressed in four randomized controlled trials and one retrospective study testing the use of MTX plus oral GCs (initial prednisone doses ranging from 15 to 25 mg/day) (24–27,51). There was moderate to high quality of evidence (QoE) from studies indicating a benefit of MTX regarding remission (1 study) (27), relapse rate (1 study) (24), discontinuation of GC (1 study) (24) and cumulative GC doses (3 studies) (24,26,27). Evidence from one to four studies (1 related to remission, 4 to relapse, 1 to discontinuation of GC) indicating no benefit regarding these outcomes was of very low quality (25–27,51).

The reasons why the panel did not support a stronger recommendation for the use of MTX in PMR are the following: 1) the total number of patients investigated in randomized trials was small (n=194) (24–27), hence further confirmation of the present data is necessary; 2) results were contradictory in part, although trials with a negative result had a very low QoE; 3) a reduction in GC-related adverse events with the use of MTX has not been demonstrated. The power of the prospective studies to address this outcome, however, was insufficient. The panel nevertheless felt that earlier discontinuation of GC (24) and a lower cumulative GC dose in MTX users (26,27) decreases the likelihood of GC-related side effects; and 4) the cost-effectiveness of MTX use in PMR is not clear. More frequent prescriptions of MTX may lead to higher utilization of healthcare resources in the short term (eg, because of specialist referral, monitoring visits, blood tests, etc.) but may in the long term save costs by reducing GC-related side effects. Future studies are necessary to clarify this issue.

The group recognized that no recommendation can be made for the use of other non-biologic (ie, conventional synthetic and conventional targeted) DMARDs in PMR because of the lack of good evidence from PMR studies. Hydroxychloroquine was investigated by a single very low QoE retrospective study reporting no benefit regarding relapse rate (51).

Recommendation 8: (PICOs 10–11) The panel strongly recommends against the use of TNFα blocking agents for the treatment of PMR.

The group agreed strongly against the use of TNFα blocking agents in PMR at this time since there is no evidence for benefit, but there is a considerable risk of potential harm and high resource use (55).

No recommendation can be made for other biologic agents as no prospective trials have been published so far. There is one ongoing randomized study on the

use of tocilizumab (clinicaltrials.gov NCT01396317) and another three-arm trial comparing secukinumab, canakinumab and GCs (clinicaltrials.gov NCT01364389) in PMR. The results of these studies may lead to a modification of this recommendation.

Recommendation 9: (PICO 12) The panel conditionally recommends considering an individualized exercise program for PMR patients aimed at the maintenance of muscle mass and function, and reducing risk of falls.

There are no studies investigating the value of non-pharmacological therapies (eg, physiotherapy, relaxation techniques, diets, etc.) in PMR and there is insufficient clinical experience on this issue to agree on a specific recommendation. Nevertheless, the panel agreed on recommending an individualized exercise program (see overarching principles) in view of its benefit for maintaining muscle mass and function and reducing risk of falls, especially in older persons on long-term GCs as well as in frail patients.

Use of herbal preparations in PMR. The panel strongly recommends against the use of the Chinese herbal preparations Yanghe and Biqi capsules in PMR patients.

There were some discussions about whether herbal preparations could be considered non-pharmacological interventions (and were therefore within the scope of PICO 12); however, the panel felt the need for comment on this issue because several preparations are available which may be popular with PMR patients.

The SLR identified two studies testing Chinese Yanghe herb decoction and Chinese Biqi capsules in PMR patients (56,57). For Chinese Yanghe there is moderate QoE for a lower ESR at week 8 (mean difference 6.0 mm/hour) and 12 (6.4 mm/hour) and very low QoE indicating a lower rate of GC-related adverse events (with borderline significance of the effect estimate) as well as reduced morning stiffness at week 12 (56). For Biqi capsules there is low QoE indicating a higher response rate at week 12 (57).

The group nevertheless agreed (after balancing evidence, benefit/harm, availability and resource use) to recommend strongly against the regular use of these preparations at this time for the following reasons: 1) the relevance of the small effect of Chinese Yanghe herb decoction on ESR is minimal for patients and good evidence for a clinical benefit of the substance is not available; 2) neither of the two substances is approved by the US Food and Drug Administration (FDA) or the European Medicines Agency (EMA); 3) the generalizability of the evidence for benefit is unclear; 4) these preparations may have unforeseeable adverse effects; 5) the availability of high quality preparations is unclear; and 6) resource impact (ie, costs) is unknown.

Release and implementation of the recommendations. See online supplementary file S2, on the *Arthritis & Rheumatology* web site at http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract.

Cost implications and conflicts of interest. Cost implications are outside the scope of these recommendations.

None of the panel members disclosed any conflict of interest associated with the development of these recommendations.

Discussion

See online supplementary file S3 (http://onlinelibrary.wiley.com/doi/10.1002/art.39333/abstract) for a full-length discussion. The 2015 EULAR/ACR recommendations for the management of PMR is the first collaborative project between EULAR and ACR to endorse treatment recommendations in rheumatology.

We recognize that our recommendations are only partially supported by evidence, and that they do not cover all aspects important for the management of PMR. The group therefore unanimously agreed that the research agenda (containing the evidence gaps related to PMR management) is an important result of this project (Box 2).

Due to our rigorous SLR approach to select high quality papers, we did not include other reviews, case reports or case series indicating possible treatment options in treatment-resistant PMR patients. For example, we found one earlier SLR reporting similar conclusions regarding the value of MTX in PMR (58). In addition, two case series were recently published on the use of leflunomide (59,60) and a few case reports are available on tocilizumab (61–63). Azathioprine has been tested in a double-blind randomized controlled trial in patients with PMR and GCA; however, as PMR patients were not analyzed separately, we did not include this study in the SLR (64).

It was beyond the scope of this recommendation project to define treatment targets in PMR. "Clinical improvement" was considered as the first treatment goal after the initiation of GCs, and the response criteria used in the 2012 classification criteria study may be considered (3,4). Remission and relapse have been heterogeneously defined in the literature, as we pointed out previously (65). Future prospective studies aimed at the validation of new definitions of response, remission and relapse are, therefore, required to enable a targeted treatment approach in PMR (66).

The most important limitations of this project are the paucity of high quality trials (as mentioned above) and the fact that GRADE is less well developed for the assessment of rare outcomes. Consequently, the QoE for

adverse events is usually lower than for efficacy data. This necessitated the use of relevant external evidence to strengthen this aspect of our recommendations.

These recommendations should support clinicians to achieve the best patient outcomes. Further research on existing drugs is necessary to offer additional, evidence-based treatment options to our patients. We anticipate an update of these recommendations 3 years after their publication; however, an earlier revision may be necessary if new data emerge that would modify the current recommendations.

ACKNOWLEDGMENT

We thank Catherine Wardle from Southend library for her assistance retrieving full text articles.

AUTHOR CONTRIBUTIONS

All authors contributed to conception and design of the study, acquisition and/or interpretation of data, drafting the article or revising it critically for important intellectual content, and approved the final version of the manuscript. All authors had full access to all of the data (including statistical reports and tables) in the study and can take responsibility for the integrity of the data and the accuracy of the data analysis.
